Paralinearization of the Dirichlet to Neumann operator, and regularity of three-dimensional water waves

Thomas Alazard [*]   Guy Métivier [†]

Abstract

This paper is concerned with *a priori* C^∞ regularity for three-dimensional doubly periodic travelling gravity waves whose fundamental domain is a symmetric diamond. The existence of such waves was a long standing open problem solved recently by Iooss and Plotnikov. The main difficulty is that, unlike conventional free boundary problems, the reduced boundary system is not elliptic for three-dimensional pure gravity waves, which leads to small divisors problems. Our main result asserts that sufficiently smooth diamond waves which satisfy a diophantine condition are automatically C^∞. In particular, we prove that the solutions defined by Iooss and Plotnikov are C^∞. Two notable technical aspects are that (i) no smallness condition is required and (ii) we obtain an exact paralinearization formula for the Dirichlet to Neumann operator.

1 Introduction

The question is to prove the *a priori* regularity of known travelling waves solutions to the water waves equations. We here start an analysis of this problem for diamond waves, which are three-dimensional doubly periodic travelling gravity waves whose fundamental domain is a symmetric diamond. The existence of such waves was established by Iooss and Plotnikov in a recent beautiful memoir ([22]).

After some standard changes of unknowns which are recalled below in §2.1, for a wave travelling in the direction Ox_1, we are led to a system of two scalar equations which reads

$$\begin{cases} G(\sigma)\psi - \partial_{x_1}\sigma = 0, \\ \mu\sigma + \partial_{x_1}\psi + \dfrac{1}{2}\left|\nabla\psi\right|^2 - \dfrac{1}{2}\dfrac{\left(\nabla\sigma\cdot\nabla\psi + \partial_{x_1}\sigma\right)^2}{1+|\nabla\sigma|^2} = 0, \end{cases} \tag{1.1}$$

where the unknowns are $\sigma, \psi \colon \mathbf{R}^2 \to \mathbf{R}$, μ is a given positive constant and $G(\sigma)$ is the Dirichlet to Neumann operator, which is defined by

$$G(\sigma)\psi(x) = \sqrt{1+|\nabla\sigma|^2}\,\partial_n\phi|_{y=\sigma(x)} = (\partial_y\phi)(x,\sigma(x)) - \nabla\sigma(x)\cdot(\nabla\phi)(x,\sigma(x)),$$

where $\phi = \phi(x,y)$ is the solution of the Laplace equation

$$\Delta_{x,y}\phi = 0 \quad \text{in} \quad \Omega := \{\,(x,y) \in \mathbf{R}^2 \times \mathbf{R} \,|\, y < \sigma(x)\,\}, \tag{1.2}$$

with boundary conditions

$$\phi(x,\sigma(x)) = \psi(x), \quad \nabla_{x,y}\phi(x,y) \to 0 \text{ as } y \to -\infty. \tag{1.3}$$

Diamond waves are the simplest solutions of (1.1) one can think of. These 3D waves come from the nonlinear interaction of two simple oblique waves with the same amplitude. Henceforth, by definition, Diamond waves are solutions (σ,ψ) of System (1.1) such that: (i) σ, ψ are doubly-periodic with period 2π in x_1 and period $2\pi\ell$ in x_2 for some fixed $\ell > 0$ and (ii) σ is even in x_1 and even in x_2; ψ is odd in x_1 and even in x_2 (cf Definition 2.2).

It was proved by H. Lewy [29] in the fifties that, in the two-dimensional case, if the free boundary is a C^1 curve, then it is a C^ω curve (see also the independent papers of Gerber [15, 16, 17]). Craig and Matei obtained an analogous result for three-dimensional (i.e. for a 2D surface) capillary gravity waves in [10, 11]. For the study of *pure gravity waves* the main difficulty is that System (1.1) is *not elliptic*. Indeed, it is well known that $G(0) = |D_x|$ (cf §2.5). This implies that the determinant of the symbol of the linearized system at the trivial solution $(\sigma,\psi) = (0,0)$ is

$$\mu|\xi| - \xi_1^2,$$

so that the characteristic variety $\{\xi \in \mathbf{R}^2 \,:\, \mu|\xi| - \xi_1^2 = 0\}$ is unbounded.

This observation contains the key dichotomy between two-dimensional waves and three-dimensional waves. Also, it explains why the problem is much more intricate for pure gravity waves (cf §7.2 where we prove *a priori* regularity for capillary waves by using the ellipticity given by surface tension). More importantly, it suggests that the main technical issue is that small divisors enter into the analysis of three-dimensional waves, as observed by Plotnikov in [36] and Craig and Nicholls in [12].

In [22], Iooss and Plotnikov give a bound for the inverse of the symbol of the linearized system at a non trivial point under a diophantine condition, which is the key ingredient to prove the existence of non trivial solutions to (1.1) by means of a Nash-Moser scheme. Our main result, which is Theorem 2.5, asserts that sufficiently smooth diamond waves which satisfy a refined variant of their diophantine condition are automatically C^∞. We shall prove that there are three functions ν, κ_0, κ_1 defined on the set of H^{12} diamond waves such that, if for some $0 \le \delta < 1$ there holds

$$\left| k_2 - \left(\nu(\mu,\sigma,\psi) k_1^2 + \kappa_0(\mu,\sigma,\psi) + \frac{\kappa_1(\mu,\sigma,\psi)}{k_1^2} \right) \right| \ge \frac{1}{k_1^{2+\delta}},$$

for all but finitely many $(k_1, k_2) \in \mathbf{N}^2$, then $(\sigma,\psi) \in C^\infty$. Two interesting features of this result are that, firstly *no smallness condition is required*, and secondly this diophantine condition is weaker than the one which ensures that the solutions of Iooss and Plotnikov exist.

The main corollary of this theorem states that the solutions of Iooss and Plotnikov are C^∞. Namely, consider the family of solutions whose existence was established in [22]. These diamond waves are of the form

$$\begin{aligned} \sigma^\varepsilon(x) &= \varepsilon\sigma_1(x) + \varepsilon^2\sigma_2(x) + \varepsilon^3\sigma_3(x) + O(\varepsilon^4), \\ \psi^\varepsilon(x) &= \varepsilon\psi_1(x) + \varepsilon^2\psi_2(x) + \varepsilon^3\psi_3(x) + O(\varepsilon^4), \\ \mu^\varepsilon &= \mu_c + \varepsilon^2\mu_1 + O(\varepsilon^4), \end{aligned} \tag{1.4}$$

where $\varepsilon \in [0, \varepsilon_0]$ is a small parameter and

$$\mu_c := \frac{\ell}{\sqrt{1+\ell^2}}, \ \sigma_1(x) := -\frac{1}{\mu_c}\cos x_1 \cos\left(\frac{x_2}{\ell}\right), \ \psi_1(x) := \sin x_1 \cos\left(\frac{x_2}{\ell}\right),$$

so that $(\sigma_1, \psi_1) \in C^\infty(\mathbf{T}^2)$ solves the linearized system around the trivial solution $(0,0)$. Then it follows from the small divisors analysis in [22] and Theorem 2.5 below that $(\sigma^\varepsilon, \psi^\varepsilon) \in C^\infty$.

The main novelty is to perform a full paralinearization of System (1.1). A notable technical aspect is that we obtain exact identities with remainders having optimal regularity. This approach depends on a careful study of the Dirichlet to Neumann operator, which is inspired by the important paper of Lannes [27]. The corresponding result about the paralinearization of the Dirichlet to Neumann operator is stated in Theorem 2.12. This strategy has a number of consequences. For instance, we shall see that this approach simplifies the analysis of the diophantine condition (see Remark 6.3 in §6). Also, one might in a future work use Theorem 2.12 to prove the existence of the solutions without the Nash–Moser iteration scheme. These observations might be useful in a wider context. Indeed, it is easy to prove a variant of Theorem 2.12 for time-dependent free boundaries. With regards to the analysis of the Cauchy problem for the water waves, this tool reduces the proof of some difficult nonlinear estimates to easy symbolic calculus questions for symbols.

2 Main results

2.1 The equations

We denote the spatial variables by $(x, y) = (x_1, x_2, y) \in \mathbf{R}^2 \times \mathbf{R}$ and use the notations

$$\nabla = (\partial_{x_1}, \partial_{x_2}), \quad \Delta = \partial_{x_1}^2 + \partial_{x_2}^2, \quad \nabla_{x,y} = (\nabla, \partial_y), \quad \Delta_{x,y} = \partial_y^2 + \Delta.$$

We consider a three-dimensional gravity wave travelling with velocity c on the free surface of an infinitely deep fluid. Namely, we consider a solution of the three-dimensional incompressible Euler equations for an irrotational flow in a domain of the form

$$\Omega = \{ (x, y) \in \times \mathbf{R}^2 \times \mathbf{R} \,|\, y < \sigma(x) \},$$

whose boundary is a free surface, which means that σ is an unknown (think of an interface between air and water). The fact that we consider an incompressible, irrotational flow implies that the velocity field is the gradient of a potential which is an harmonic function. The equations are then given by two boundary conditions: a kinematic condition which states that the free surface moves with the fluid, and a dynamic condition that expresses a balance of forces across the free surface. The classical system reads

$$\begin{cases} \partial_y^2 \phi + \Delta \phi = 0 & \text{in } \Omega, \\ \partial_y \phi - \nabla \sigma \cdot \nabla \phi - c \cdot \nabla \sigma = 0 & \text{on } \partial\Omega, \\ g\sigma + \dfrac{1}{2} |\nabla \phi|^2 + \dfrac{1}{2} (\partial_y \phi)^2 + c \cdot \nabla \phi = 0 & \text{on } \partial\Omega, \\ (\nabla \phi, \partial_y \phi) \to (0, 0) & \text{as } y \to -\infty, \end{cases} \tag{2.1}$$

where the unknowns are $\phi \colon \Omega \to \mathbf{R}$ and $\sigma \colon \mathbf{R}^2 \to \mathbf{R}$, $c \in \mathbf{R}^2$ is the wave speed and $g > 0$ is the acceleration of gravity.

A popular form of the water waves equations is obtained by working with the trace of ϕ at the free boundary. Define $\psi \colon \mathbf{R}^2 \to \mathbf{R}$ by

$$\psi(x) := \phi(x, \sigma(x)).$$

The idea of introducing ψ goes back to Zakharov. It allows us to reduce the problem to the analysis of a system of two equations on σ and ψ which are defined on $\mathbf{R}^2$. The most direct computations show that (σ, ψ) solves

$$\begin{cases} G(\sigma)\psi - c \cdot \nabla \sigma = 0, \\ g\sigma + c \cdot \nabla \psi + \dfrac{1}{2} |\nabla \psi|^2 - \dfrac{1}{2} \dfrac{\left(\nabla \sigma \cdot \nabla \psi + c \cdot \nabla \sigma\right)^2}{1 + |\nabla \sigma|^2} = 0. \end{cases}$$

Up to rotating the axes and replacing g by $\mu := g/\left|c\right|^2$ one may assume that

$$c = (1,0),$$

thereby obtaining System (1.1).

Remark 2.1. Many variations are possible. In §7.2 we study capillary gravity waves. Also, we consider in §7.1 the case with source terms.

2.2 Regularity of three-dimensional diamond waves

Now we specialize to the case of diamond patterns. Namely we consider solutions which are periodic in both horizontal directions, of the form

$$\begin{aligned}\sigma(x) &= \sigma(x_1 + 2\pi, x_2) = \sigma\left(x_1, x_2 + 2\pi\ell\right),\\ \psi(x) &= \psi(x_1 + 2\pi, x_2) = \psi\left(x_1, x_2 + 2\pi\ell\right),\end{aligned}$$

and which are symmetric with respect to the direction of propagation Ox_1.

Definition 2.2. *i) Hereafter, we fix $\ell > 0$ and denote by $\mathbf{T}^2$ the 2-torus*

$$\mathbf{T}^2 = (\mathbf{R}/2\pi\mathbf{Z}) \times (\mathbf{R}/2\pi\ell\mathbf{Z}).$$

Bi-periodic functions on $\mathbf{R}^2$ are identified with functions on $\mathbf{T}^2$, so that the Sobolev spaces of bi-periodic functions are denoted by $H^s(\mathbf{T}^2)$ ($s \in \mathbf{R}$).

ii) Given $\mu > 0$ and $s > 3$, the set $D^s_\mu(\mathbf{T}^2)$ consists of the solutions (σ, ψ) of System (1.1) which belong to $H^s(\mathbf{T}^2)$ and which satisfy, for all $x \in \mathbf{R}^2$,

$$\begin{aligned}\sigma(x) &= \sigma(-x_1, x_2) = \sigma(x_1, -x_2),\\ \psi(x) &= -\psi(-x_1, x_2) = \psi(x_1, -x_2),\end{aligned}$$

and

$$1 + (\partial_{x_1}\phi)(x, \sigma(x)) \neq 0, \tag{2.2}$$

where ϕ denotes the harmonic extension of ψ defined by (1.2)–(1.3).

iii) The set $D^s(\mathbf{T}^2)$ of H^s diamond waves is the set of all triple $\omega = (\mu, \sigma, \psi)$ such that $(\sigma, \psi) \in D^s_\mu(\mathbf{T}^2)$.

Remark 2.3. A first remark about these spaces is that they are not empty; at least since 2D waves are obviously 3D waves (independent of x_2) and since we know that 2D symmetric waves exist, as proved in the twenties by Levi-Civita [28], Nekrasov [34] and Struik [37]. The existence of *really three-dimensional pure gravity waves* was a well known problem in the theory of surface waves. It has been solved by Iooss and Plotnikov in [22]. We refer to [22, 8, 12, 18] for references and an historical survey of the background of this problem.

Remark 2.4. Two observations are in order about (2.2), which is not an usual assumption. We first note that (2.2) is a natural assumption which ensures that, in the moving frame where the waves look steady, the first component of the velocity evaluated at the free surface does not vanish (cf the proof of Lemma 5.15, which is the only step in which we use (2.2)). On the other hand, observe that (2.2) is automatically satisfied for small amplitude waves such that $\phi = O(\varepsilon)$ in C^1.

For all $s \geq 23$, Iooss and Plotnikov prove the existence of H^s-diamond waves having the above form (1.4) for $\varepsilon \in \mathcal{E}$ where $\mathcal{E} = \mathcal{E}(s, \ell)$ has asymptotically a full measure when ε tends to 0 (we refer to Theorem 2.7 below for a precise statement). The set $\mathcal{E}$ is the set of parameters $\varepsilon \in [0, \varepsilon_0]$ (with ε_0 small enough) such that a diophantine condition is satisfied. The following theorem states that solutions satisfying a refined diophantine condition are automatically C^∞. We postpone to the next paragraph for a statement which asserts that this condition is not empty. As already mentioned, a nice technical feature is that no smallness condition is required in the following statement.

Theorem 2.5. *There exist three real-valued functions* ν, κ_0, κ_1 *defined on* $D^{12}(\mathbf{T}^2)$ *such that, for all* $\omega = (\mu, \sigma, \psi) \in D^{12}(\mathbf{T}^2)$*:*

i) if there exist $\delta \in [0, 1[$ *and* $N \in \mathbf{N}^*$ *such that*

$$\left| k_2 - \left(\nu(\omega) k_1^2 + \kappa_0(\omega) + \frac{\kappa_1(\omega)}{k_1^2} \right) \right| \geq \frac{1}{k_1^{2+\delta}}, \tag{2.3}$$

for all $(k_1, k_2) \in \mathbf{N}^2$ *with* $k_1 \geq N$*, then* $(\sigma, \psi) \in C^\infty(\mathbf{T}^2)$*.*

ii) $\nu(\omega) \geq 0$ *and there holds the estimate*

$$\begin{aligned}\left| \nu(\omega) - \frac{1}{\mu} \right| + \left| \kappa_0(\omega) - \kappa_0(\mu, 0, 0) \right| + \left| \kappa_1(\omega) - \kappa_1(\mu, 0, 0) \right| \\ \leq C \left(\| (\sigma, \psi) \|_{H^{12}} + \mu + \frac{1}{\mu} \right) \| (\sigma, \psi) \|_{H^{12}}^2 ,\end{aligned}$$

for some non-decreasing function C *independent of* (μ, σ, ψ)*.*

Remark 2.6. i) To define the coefficients $\nu(\omega), \kappa_0(\omega), \kappa_1(\omega)$ we shall use the principal, sub-principal and sub-sub-principal symbols of the Dirichlet to Neumann operator. This explains the reason why we need to know that (σ, ψ) belongs at least to H^{12} in order to define these coefficients.

ii) The important thing to note about the estimate is that it is second order in $\| (\sigma, \psi) \|_{H^{12}}$. This plays a crucial role to prove that small amplitude solutions exist (see the discussion preceding Proposition 2.10).

2.3 The small divisor condition for small amplitude waves

The properties of an ocean surface wave are easily obtained assuming the wave has an infinitely small amplitude (linear Airy theory). To find nonlinear waves of small amplitude, one seeks solutions which are small perturbations of small amplitude solutions of the linearized system at the trivial solution $(0,0)$. To do this, a basic strategy which goes back to Stokes is to expand the waves in a power series of the amplitude ε. In [22], the authors use a third order nonlinear theory to find 3D-diamond waves (this means that they consider solutions of the form (2.5)). We now state the main part of their results (see [22] for further comments).

Theorem 2.7 (from [22])**.** *Let $\ell > 0$ and $s \geq 23$, and set $\mu_c = \frac{\ell}{\sqrt{1+\ell^2}}$. There is a set $A \subset [0,1]$ of full measure such that, if $\mu_c \in A$ then there exists a set $\mathcal{E} = \mathcal{E}(s,\mu_c)$ satisfying*

$$\lim_{r\to 0} \frac{2}{r^2} \int_{\mathcal{E}\cap[0,r]} t\,dt = 1, \tag{2.4}$$

such that there exists a family of diamond waves $(\mu^\varepsilon, \sigma^\varepsilon, \psi^\varepsilon) \in D^s(\mathbf{T}^2)$ with $\varepsilon \in \mathcal{E}$, of the special form

$$\begin{aligned} \sigma^\varepsilon(x) &= \varepsilon\sigma_1(x) + \varepsilon^2\sigma_2(x) + \varepsilon^3\sigma_3(x) + \varepsilon^4\Sigma^\varepsilon(x),\\ \psi^\varepsilon(x) &= \varepsilon\psi_1(x) + \varepsilon^2\psi_2(x) + \varepsilon^3\psi_3(x) + \varepsilon^4\Psi^\varepsilon(x),\\ \mu^\varepsilon &= \mu_c + \varepsilon^2\mu_1 + O(\varepsilon^4), \end{aligned} \tag{2.5}$$

where $\sigma_1, \sigma_2, \sigma_3, \psi_1, \psi_2, \psi_3 \in H^\infty(\mathbf{T}^2)$ with

$$\sigma_1(x) = -\frac{1}{\mu_c}\cos x_1 \cos\Big(\frac{x_2}{\ell}\Big), \quad \psi_1(x) = \sin x_1 \cos\Big(\frac{x_2}{\ell}\Big),$$

the remainders $\Sigma^\varepsilon, \Psi^\varepsilon$ are uniformly bounded in $H^s(\mathbf{T}^2)$ and

$$\mu_1 = \frac{1}{4\mu_c^3} - \frac{1}{2\mu_c^2} - \frac{3}{4\mu_c} + 2 + \frac{\mu_c}{2} - \frac{9}{4(2-\mu_c)}.$$

To prove this result, the main difficulty is to give a bound for the inverse of the symbol of the linearized system at a non trivial point. Due to the occurence of small divisors, this is proved in [22] under a diophantine condition. Now, it follows from the small divisors analysis by Iooss and Plotnikov in [22] that, for all $\varepsilon \in \mathcal{E}$,

$$\Big| k_2 - \Big(\nu(\mu^\varepsilon, \sigma^\varepsilon, \psi^\varepsilon)k_1^2 + \kappa_0(\mu^\varepsilon, \sigma^\varepsilon, \psi^\varepsilon)\Big)\Big| \geq \frac{c}{k_1^2},$$

for some positive constant c and all $k = (k_1, k_2)$ such that $k \neq 0, k \neq \pm(1,1)$, $k \neq \pm(-1,1)$. As a result, Theorem 2.5 implies that, for all $\varepsilon \in \mathcal{E}$,

$$(\sigma^\varepsilon, \psi^\varepsilon) \in C^\infty(\mathbf{T}^2).$$

The main question left open here is to prove that, in fact, $(\sigma^\varepsilon, \psi^\varepsilon)$ is analytic or at least have some maximal Gevrey regularity.

To prove Theorem 2.7, the first main step in [22] is to define approximate solutions. Then, Iooss and Plotnikov used a Nash–Moser iterative scheme to prove that there exist exact solutions near these approximate solutions. Recall that the Nash method allows to solve functional equations of the form $\Phi(u) = \Phi(u_0) + f$ in situations where there are loss of derivatives so that one cannot apply the usual implicit function Theorem. It is known that the solutions thus obtained are smooth provided that f is smooth (cf Theorem 2.2.2 in [19]). This remark raises a question: Why the solutions constructed by Iooss and Plotnikov are not automatically smooth? This follows from the fact that the problem depends on the parameter ε and hence one is led to consider functional equations of the form $\Phi(u, \varepsilon) = \Phi(u_0, \varepsilon) + f$. In this context, the estimates established in [22] allow to prove that, for any $\ell \in \mathbf{N}$, one can define solutions $(\sigma, \psi) \in C^\ell(\mathbf{T}^2)$ for $\varepsilon \in \mathcal{E} \cap [0, \varepsilon_0]$, for some positive constant ε_0 depending on ℓ.

The previous discussion raises a second question. Indeed, to prove that the solutions exist one has to establish uniform estimates in the following sense: one has to prove that some diophantine condition is satisfied for all k such that k_1 is greater than a *fixed* integer independent of ε. In [22], the authors establish such a result by using an ergodic argument. We shall explain how to perform this analysis by means of our refined diophantine condition. This step depends in a crucial way on the fact that the estimate of $\nu(\mu, \sigma, \psi) - \nu(\mu, 0, 0)$, $\kappa_0(\mu, \sigma, \psi) - \kappa_0(\mu, 0, 0)$ and $\kappa_1(\mu, \sigma, \psi) - \kappa_1(\mu, 0, 0)$ are of second order in the amplitude. Namely, we make the following assumption.

Assumption 2.8. Let $\nu = \nu(\varepsilon)$, $\kappa_0 = \kappa_0(\varepsilon)$ and $\kappa_1 = \kappa_1(\varepsilon)$ be three real-valued functions defined on $[0, 1]$. In the following proposition it is assumed that

$$\begin{aligned} \nu(\varepsilon) &= \underline{\nu} + \underline{\nu}'\varepsilon^2 + \varepsilon\varphi_1(\varepsilon^2), \\ \kappa_0(\varepsilon) &= \underline{\kappa_0} + \varphi_2(\varepsilon^2), \\ \kappa_1(\varepsilon) &= \underline{\kappa_1} + \varphi_3(\varepsilon^2), \end{aligned} \tag{2.6}$$

for some constants $\underline{\nu}, \underline{\nu}', \underline{\kappa_0}, \underline{\kappa_1}'$ with

$$\underline{\nu}' \neq 0,$$

and three Lipschitz functions $\varphi_j \colon [0, 1] \to \mathbf{R}$ satisfying $\varphi_j(0) = 0$.

Remark 2.9. In [22], the authors prove that the assumption $\underline{\nu}' \neq 0$ is satisfied for $\nu(\varepsilon) = \nu(\mu^\varepsilon, \sigma^\varepsilon, \psi^\varepsilon)$ where $(\mu^\varepsilon, \sigma^\varepsilon, \psi^\varepsilon)$ are the solutions of Theorem 2.7. Assumption 2.8 is satisfied by these solutions.

Proposition 2.10. *Let* δ *and* δ' *be such that*

$$1 > \delta > \delta' > 0.$$

Assume in addition to Assumption 2.8 that there exists $n \geq 2$ *such that*

$$\left| k_2 - \underline{\nu} k_1^2 - \underline{\kappa_0} \right| \geq \frac{1}{k_1^{1+\delta'}}, \tag{2.7}$$

for all $k \in \mathbf{N}^2$ *with* $k_1 \geq n$. *Then there exist* $K > 0$, $r_0 > 0$, $N_0 \in \mathbf{N}$ *and a set* $\mathcal{A} \subset [0,1]$ *satisfying*

$$\forall r \in [0, r_0], \quad \frac{1}{r} \left| \mathcal{A} \cap [0, r] \right| \geq 1 - K r^{\frac{\delta - \delta'}{3 + \delta'}}, \tag{2.8}$$

such that, if $\varepsilon^2 \in \mathcal{A}$ *and* $k_1 \geq N_0$ *then*

$$\left| k_2 - \nu(\varepsilon) k_1^2 - \kappa_0(\varepsilon) - \frac{\kappa_1(\varepsilon)}{k_1^2} \right| \geq \frac{1}{k_1^{2+\delta}}, \tag{2.9}$$

for all $k_2 \in \mathbf{N}$.

Remark 2.11. (*i*) It follows from the classical argument introduced by Borel in [7] that there exists a null set $\mathcal{N} \subset [0,1]$ such that, for all $(\underline{\nu}, \underline{\kappa_0}) \in ([0,1] \setminus \mathcal{N}) \times [0,1]$, the inequality (2.7) is satisfied for all (k_1, k_2) with k_1 sufficiently large.

(*ii*) If $\mathcal{A}$ satisfies (2.8) then the set $\mathcal{E} = \{\varepsilon \in [0,1] : \varepsilon^2 \in \mathcal{A}\}$ satisfies (2.4). The size of set of those parameters ε such that the diophantine condition (2.9) is satisfied is bigger than the size of the set $\mathcal{E}$ given by Theorem 2.7.

Proposition 2.10 is proved in Section 6.

2.4 Paralinearization of the Dirichlet to Neumann operator

To prove Theorem 2.5, we use the strategy of Iooss and Plotnikov [22]. The main novelty is that we paralinearize the water waves system. This approach depends on a careful study of the Dirichlet to Neumann operator, which is inspired by a paper of Lannes [27].

Since this analysis has several applications (for instance to the study of the Cauchy problem), we consider the general multi-dimensional case and we do not assume that the functions have some symmetries. We consider here a domain Ω of the form

$$\Omega = \{ (x, y) \in \mathbf{T}^d \times \mathbf{R} \,|\, y < \sigma(x) \},$$

where $\mathbf{T}^d$ is any d-dimensional torus with $d \geq 1$. Recall that, by definition, the Dirichlet to Neumann operator is the operator $G(\sigma)$ given by

$$G(\sigma)\psi = \sqrt{1+|\nabla\sigma|^2}\,\partial_n\varphi|_{y=\sigma(x)},$$

where n is the exterior normal and φ is given by

$$\Delta_{x,y}\varphi = 0, \quad \varphi|_{y=\sigma(x)} = \psi, \quad \nabla_{x,y}\varphi \to 0 \text{ as } y \to -\infty. \tag{2.10}$$

To clarify notations, the Dirichlet to Neumann operator is defined by

$$(G(\sigma)\psi)(x) = (\partial_y\varphi)(x,\sigma(x)) - \nabla\sigma(x)\cdot(\nabla\varphi)(x,\sigma(x)). \tag{2.11}$$

Thus defined, $G(\sigma)$ differs from the usual definition of the Dirichlet to Neumann operator because of the scaling factor $\sqrt{1+|\nabla\sigma|^2}$; yet, as in [27, 22] we use this terminology for the sake of simplicity.

It is known since Calderón that, if σ is a given C^∞ function, then the Dirichlet to Neumann operator $G(\sigma)$ is a classical pseudo-differential operator, elliptic of order 1 (see [3, 38, 39, 43]). We have

$$G(\sigma)\psi = \mathrm{Op}(\lambda_\sigma)\psi,$$

where the symbol λ_σ has the asymptotic expansion

$$\lambda_\sigma(x,\xi) \sim \lambda_\sigma^1(x,\xi) + \lambda_\sigma^0(x,\xi) + \lambda_\sigma^{-1}(x,\xi) + \cdots \tag{2.12}$$

where λ_σ^k are homogeneous of degree k in ξ, and the principal symbol λ_σ^1 is elliptic of order 1, given by

$$\lambda_\sigma^1(x,\xi) = \sqrt{(1+|\nabla\sigma(x)|^2)\,|\xi|^2 - (\nabla\sigma(x)\cdot\xi)^2}. \tag{2.13}$$

Moreover, the symbols $\lambda_\sigma^0, \lambda_\sigma^{-1}, \dots$ are defined by induction so that one can easily check that λ_σ^k involves only derivatives of σ of order $\leq |k|+2$ (see [3]).

There are also various results when $\sigma \notin C^\infty$. Expressing $G(\sigma)$ as a singular integral operator, it was proved by Craig, Schanz and C. Sulem [13] that

$$\sigma \in C^{k+1},\ \psi \in H^{k+1} \text{ with } k \in \mathbf{N} \Rightarrow G(\sigma)\psi \in H^k. \tag{2.14}$$

Moreover, when σ is a given function with limited smoothness, it is known that $G(\sigma)$ is a pseudo-differential operator with symbol of limited regularity[1] (see [41, 14]). In this direction, for $\sigma \in H^{s+1}(\mathbf{T}^2)$ with s large enough, it follows from the analysis by Lannes ([27]) and a small additional work that

$$G(\sigma)\psi = \mathrm{Op}(\lambda_\sigma^1)\psi + r(\sigma,\psi), \tag{2.15}$$

---

[1] We do not explain here the way we define pseudo-differential operators with symbols of limited smoothness since this problem will be fixed by using paradifferential operators, and since all that matters in (2.15) is the regularity of the remainder term $r(\sigma,\psi)$.

where the remainder $r(\sigma,\psi)$ is such that

$$\psi \in H^s(\mathbf{T}^d) \Rightarrow r(\sigma,\psi) \in H^s(\mathbf{T}^d).$$

For the analysis of the water waves, the think of great interest here is that this gives a result for $G(\sigma)\psi$ when σ and ψ have exactly the same regularity. Indeed, (2.15) implies that, if $\sigma \in H^{s+1}(\mathbf{T}^d)$ and $\psi \in H^{s+1}(\mathbf{T}^d)$ for some s large enough, then $G(\sigma)\psi \in H^s(\mathbf{T}^d)$. This result was first established by Craig and Nicholls in [12] and Wu in [45, 46] by different methods. We refer to [27] for comments on the estimates associated to these regularity results as well as to [4] for the rather different case where one considers various dimensional parameters.

A fundamental difference with these results is that we shall determine the full structure of $G(\sigma)$ by performing a full paralinearization of $G(\sigma)\psi$ with respect to ψ and σ. A notable technical aspect is that we obtain exact identities where the remainders have optimal regularity. We shall establish a formula of the form

$$G(\sigma)\psi = \operatorname{Op}(\lambda_\sigma)\psi + B(\sigma,\psi) + R(\sigma,\psi),$$

where $B(\sigma,\psi)$ shall be given explicitly and $R(\sigma,\psi) \sim 0$ in the following sense: $R(\sigma,\psi)$ is twice more regular than σ and ψ.

Before we state our result, two observations are in order.

Firstly, observe that we can extend the definition of λ_σ for $\sigma \notin C^\infty$ in the following obvious manner: we consider in the asymptotic expansion (2.12) only the terms which are meaningful. This means that, for $\sigma \in C^{k+2} \setminus C^{k+3}$ with $k \in \mathbf{N}$, we set

$$\lambda_\sigma(x,\xi) = \lambda_\sigma^1(x,\xi) + \lambda_\sigma^0(x,\xi) + \cdots + \lambda_\sigma^{-k}(x,\xi). \tag{2.16}$$

We associate operators to these symbols by means of the paradifferential quantization (we recall the definition of paradifferential operators in §4.1).

Secondly, recall that a classical idea in free boundary problems is to use a change of variables to reduce the problem to a fixed domain. This suggests to map the graph domain Ω to a half space via the correspondence

$$(x,y) \mapsto (x,z) \quad \text{where} \quad z = y - \sigma(x).$$

This change of variables takes $\Delta_{x,y}$ to a strictly elliptic operator and ∂_n to a vector field which is transverse to the boundary $\{z=0\}$. Namely, introduce $v \colon \mathbf{T}^d \times]-\infty,0] \to \mathbf{R}$ defined by

$$v(x,z) = \varphi(x, z+\sigma(x)),$$

so that v satisfies

$$v|_{z=0} = \varphi|_{y=\sigma(x)} = \psi,$$

and

$$(1+|\nabla\sigma|^2)\partial_z^2 v+\Delta v-2\nabla\sigma\cdot\nabla\partial_z v-\partial_z v\Delta\sigma=0, \tag{2.17}$$

in the fixed domain $\mathbf{T}^d\times]-\infty,0[$. Then,

$$G(\sigma)\psi=(1+|\nabla\sigma|^2)\partial_z v-\nabla\sigma\cdot\nabla v\Big|_{z=0}. \tag{2.18}$$

Since v solves the strictly elliptic equation (2.17) with the Dirichlet boundary condition $v|_{z=0}=\psi$, there is a clear link between the regularity of ψ and the regularity of v. We formulate this link in Remark 2.13 below. However, to state our result, the assumptions are better formulated in terms of σ and v. Indeed, this enables us to state a result which remains valid for the case of finite depth. The trick is that, even if v is defined for $(x,z)\in\mathbf{T}^d\times]-\infty,0]$, we shall make an assumption on $v|_{\mathbf{T}^d\times[-1,0]}$ only (we can replace -1 by any negative constant). Below, we denote by $C^0([-1,0];H^r(\mathbf{T}^d))$ the space of functions which are continuous in $z\in[-1,0]$ with values in $H^r(\mathbf{T}^d)$.

Theorem 2.12. *Let $d\geq 1$ and $s\geq 3+d/2$ be such that $s-d/2\notin\mathbf{N}$. If*

$$\sigma\in H^s(\mathbf{T}^d),\quad v\in C^0([-1,0];H^s(\mathbf{T}^d)),\quad \partial_z v\in C^0([-1,0];H^{s-1}(\mathbf{T}^d)), \tag{2.19}$$

then

$$G(\sigma)\psi=T_{\lambda_\sigma}(\psi-T_{\mathfrak{b}}\sigma)-T_V\cdot\nabla\sigma-T_{\operatorname{div}V}\sigma+R(\sigma,\psi), \tag{2.20}$$

where T_a denotes the paradifferential operator with symbol a (cf §4.1), the function $\mathfrak{b}=\mathfrak{b}(x)$ and the vector field $V=V(x)$ belong to $H^{s-1}(\mathbf{T}^d)$, the symbol $\lambda_\sigma\in\Sigma^1_{s-1-d/2}(\mathbf{T}^d)$ (see Definition 4.3) is given by (2.16) *applied with $k=s-2-d/2$, and $R(\sigma,\psi)$ is twice more regular than the unknowns:*

$$\forall\varepsilon>0,\quad R(\sigma,\psi)\in H^{2s-2-\frac{d}{2}-\varepsilon}(\mathbf{T}^d). \tag{2.21}$$

Explicitly, $\mathfrak{b}$ and V are given by

$$\mathfrak{b}=\frac{\nabla\sigma\cdot\nabla\psi+G(\sigma)\psi}{1+|\nabla\sigma|^2},\qquad V=\nabla\psi-\mathfrak{b}\nabla\sigma.$$

There are a few further points that should be added to Theorem 2.12.

Remark 2.13. The first point to be made is a clarification of how one passes from an assumption on (σ,v) to an assumption on (σ,ψ). As in [4], it follows from standard elliptic theory that

$$\sigma\in H^{k+\frac{1}{2}}(\mathbf{T}^d),\ \psi\in H^k(\mathbf{T}^d)\Rightarrow v\in H^{k+\frac{1}{2}}([-1,0]\times\mathbf{T}^d),$$

so that $v\in C^0([-1,0];H^k(\mathbf{T}^d))$ and $\partial_z v\in C^0([-1,0];H^{k-1}(\mathbf{T}^d))$. As a result, we can replace (2.19) by the assumption that $\sigma\in H^{s+\frac{1}{2}}(\mathbf{T}^d)$ and $\psi\in H^s(\mathbf{T}^d)$.

Remark 2.14. Theorem 2.12 still holds true for non periodic functions.

Remark 2.15. The case with which we are chiefly concerned is that of an infinitely deep fluid. However, it is worth remarking that Theorem 2.12 remains valid in the case of finite depth where one considers a domain Ω of the form

$$\Omega := \{ (x,y) \in \mathbf{T}^d \times \mathbf{R} \,|\, b(x) < y < \sigma(x) \},$$

with the assumption that b is a given smooth function such that $b + 2 \le \sigma$, and define $G(\sigma)\psi$ by (2.11) where φ is given by

$$\Delta_{x,y}\varphi = 0, \quad \varphi|_{y=\sigma(x)} = \psi, \quad \partial_n \varphi|_{y=b(x)} = 0.$$

Remark 2.16. Since the scheme of the proof of Theorem 2.12 is reasonably simple, the reader should be able to obtain further results in other scales of Banach spaces without too much work. We here mention an analogous result in Hölder spaces $C^s(\mathbf{R}^d)$ which will be used in §7.2. If

$$\sigma \in C^s(\mathbf{R}^d), \quad v \in C^0([-1,0]; C^s(\mathbf{R}^d)), \quad \partial_z v \in C^0([-1,0]; C^{s-1}(\mathbf{R}^d)),$$

for some $s \in [3, +\infty]$, then we have (2.20) with

$$\mathfrak{b} \in C^{s-1}(\mathbf{R}^d), \quad V \in C^{s-1}(\mathbf{R}^d), \quad \lambda_\sigma \in \Sigma^1_{s-1}(\mathbf{R}^d),$$

and $R(\sigma,\psi) \in C^{2s-2-\varepsilon}(\mathbf{R}^d)$ for all $\varepsilon > 0$.

Remark 2.17. We can give other expressions of the coefficients. We have

$$\mathfrak{b}(x) = (\partial_y \varphi)(x, \sigma(x)) = (\partial_z v)(x, 0),$$
$$V(x) = (\nabla \varphi)(x, \sigma(x)) = (\nabla v)(x,0) - (\partial_z v)(x,0)\nabla\sigma(x),$$

where φ is as defined in (2.10). This clearly shows that $\mathfrak{b}, V \in H^{s-1}(\mathbf{T}^d)$.

As mentioned earlier, Theorem 2.12 has a number of consequences. For instance, this permits us to reduce estimates for commutators with the Dirichlet to Neumann operator to symbolic calculus questions for symbols. Similarly, we shall use Theorem 2.12 to compute the effect of changes of variables by means of the paracomposition operators of Alinhac. As shown by Hörmander in [20], another possible application is to prove the existence of the solutions by using elementary nonlinear functional analysis instead of using the Nash–Moser iteration scheme.

The proof of Theorem 2.12 is given in §4. The heart of the entire argument is a sharp paralinearization of the interior equation performed in Proposition 4.12. To do this, following Alinhac [2], the idea is to work with the good unknown

$$\psi - T_{\mathfrak{b}}\sigma.$$

At first we may not expect to have to take this unknown into account, but it comes up on its own when we compute the linearized equations (cf §3). For the study of the linearized equations, this change of unknowns amounts to introduce $\delta\psi - \mathfrak{b}\delta\sigma$. The fact that this leads to a key cancelation was first observed by Lannes in [27].

2.5 An example

We conclude this section by discussing a classical example which is Example 3 in [23] (see [22] for an analogous discussion). Consider

$$\phi = 0 \quad \text{and} \quad \sigma = \sigma(x_2).$$

Then, for any $\sigma \in C^1$, this defines a solution of (2.1) with $g = 0$, and no further smoothness of the free boundary can be inferred. Therefore, if $g = 0$ (i.e. $\mu = 0$) then there is no *a priori* regularity.

In addition, the key dichotomy $d = 1$ or $d = 2$ is well illustrated by this example. Indeed, consider the linearized system at the trivial solution $(\sigma, \phi) = (0, 0)$. We are led to analyse the following system (cf §3):

$$\begin{cases} \Delta_{z,x} v = 0 & \text{in} \quad z < 0, \\ \partial_z v - \partial_{x_1} \sigma = 0 & \text{on} \quad z = 0, \\ \mu\sigma + \partial_{x_1} v = 0 & \text{on} \quad z = 0, \\ \nabla_{z,x} v \to 0 & \text{as } z \to -\infty. \end{cases}$$

For $\sigma = 0$, it is straightforward to compute the Dirichlet to Neumann operator $G(0)$. Indeed, we have to consider the solutions of $(|\xi|^2 - \partial_z^2)V(z) = 0$, which are bounded when $z < 0$. It is clear that V must be proportional to $e^{z|\xi|}$, so that $\partial_z V = |\xi|\, V$. Reduced to the boundary, the system thus becomes

$$\begin{cases} |D_x| v - \partial_{x_1} \sigma = 0 & \text{on} \quad z = 0, \\ \mu\sigma + \partial_{x_1} v = 0 & \text{on} \quad z = 0. \end{cases}$$

The symbol of this system is

$$\begin{pmatrix} |\xi| & -i\xi_1 \\ i\xi_1 & \mu \end{pmatrix}, \tag{2.22}$$

whose determinant is

$$\mu|\xi| - \xi_1^2. \tag{2.23}$$

If $d = 1$ (or if $\mu < 0$), this is a (quasi-)homogeneous elliptic symbol. Yet, if $d = 2$ (and $\mu > 0$), the symbol (2.23) is not elliptic. It vanishes when $\mu|\xi| = \xi_1^2$, that is when $|\xi_1| \ll |\xi_2|$. The singularities are linked to the set $\{\mu|\xi_2| = \xi_1^2\}$. We thus have a Schrödinger equation on the boundary which may propagate singularities for rational values of the parameter μ. This explains why, to prove regularity, some diophantine criterion is necessary.

To conclude, let us explain why surface tension simplifies the analysis. Had we worked instead with capillary waves, the corresponding symbol (2.22) would have read

$$\begin{pmatrix} |\xi| & -i\xi_1 \\ i\xi_1 & \mu + |\xi|^2 \end{pmatrix}.$$

The simplification presents itself: this is an elliptic matrix-valued symbol for all $\mu \in \mathbf{R}$ and all $d \geq 1$.

3 Linearization

Although it is not essential for the rest of the paper, it helps if we begin by examining the linearized equations. Our goal is twofold. First we want to prepare for the paralinearization of the equations. And second we want to explain some technical but important points related to changes of variables.

We consider the system

$$\begin{cases} \partial_y^2\phi + \Delta\phi = 0 & \text{in} \quad \{y < \sigma(x)\}, \\ \partial_y\phi - \nabla\sigma\cdot\nabla\phi - c\cdot\nabla\sigma = 0 & \text{on} \quad \{y = \sigma(x)\}, \\ \mu\sigma + \dfrac{1}{2}\left|\nabla\phi\right|^2 + \dfrac{1}{2}(\partial_y\phi)^2 + c\cdot\nabla\phi = 0 & \text{on} \quad \{y = \sigma(x)\}, \\ \nabla_{x,y}\phi \to 0 & \text{as} \quad y \to -\infty, \end{cases}$$

where $\mu > 0$ and $c \in \mathbf{R}^2$. We shall perform the linearization of this system. These computations are well known. In particular it is known that the Dirichlet to Neumann operator $G(\sigma)$ is an analytic function of σ ([9, 35]). Moreover, the shape derivative of $G(\sigma)$ was computed by Lannes [27] (see also [5, 22]). Here we explain some key cancelations differently, by means of the good unknown of Alinhac [2].

3.1 Change of variables

One basic approach toward the analysis of solutions of a boundary value problem is to flatten the boundary. To do so, most directly, one can use the following change of variables, involving the unknown σ,

$$z = y - \sigma(x), \tag{3.1}$$

which means we introduce v given by

$$v(x,z) = \phi(x, z + \sigma(x)).$$

This reduces the problem to the domain $\{-\infty < z < 0\}$.

The first elementary step is to compute the equation satisfied by the new unknown v in $\{z < 0\}$ as well as the boundary conditions on $\{z = 0\}$. We easily find the following result.

Lemma 3.1. *If ϕ and σ are C^2, then $v(x,z) = \phi(x, z + \sigma(x))$ satisfies*

$$(1 + |\nabla\sigma|^2)\partial_z^2 v + \Delta v - 2\nabla\sigma\cdot\nabla\partial_z v - \partial_z v\Delta\sigma = 0 \qquad \textit{in} \quad z < 0, \tag{3.2}$$

$$(1 + |\nabla\sigma|^2)\partial_z v - \nabla\sigma\cdot(\nabla v + c) = 0 \qquad \textit{on} \quad z = 0, \tag{3.3}$$

$$\mu\sigma + c\cdot\nabla v + \frac{1}{2}\left|\nabla v\right|^2 - \frac{1}{2}\frac{\left(\nabla\sigma\cdot(\nabla v + c)\right)^2}{1 + |\nabla\sigma|^2} = 0 \qquad \textit{on} \quad z = 0. \tag{3.4}$$

Remark 3.2. It might be tempting to use a general change of variables of the form $y = \rho(x, z)$ (as in [10, 11, 26, 27]). However, these changes of variables do not modify the behavior of the functions on $z = 0$ and hence they do not modify the Dirichlet to Neumann operator (see the discussion in [44]). Therefore, the fact that we use the most simple change of variables one can think of is an interesting feature of our approach.

Remark 3.3. By following the strategy used in [22], a key point below is to use a change of variables in the *tangential* variables, of the form $x' = \chi(x)$. In [22], this change of variables is performed before the linearization. Our approach goes the opposite direction. We shall paralinearize first and then compute the effect of this change of variables by means of paracomposition operators. This has the advantage of simplifying the computations.

3.2 Linearized interior equation

Introduce the operator

$$L := (1 + |\nabla\sigma|^2)\partial_z^2 + \Delta - 2\nabla\sigma \cdot \nabla\partial_z, \tag{3.5}$$

and set

$$\mathcal{E}(v, \sigma) := Lv - \Delta\sigma\partial_z v,$$

so that the interior equation (3.2) reads $\mathcal{E}(v, \sigma) = 0$. Denote by $\mathcal{E}'_v$ and $\mathcal{E}'_\sigma$, the linearization of $\mathcal{E}$ with respect to v and σ respectively, which are given by

$$\begin{aligned}\mathcal{E}'_v(v, \sigma)\dot{v} &:= \lim_{\varepsilon\to 0} \frac{1}{\varepsilon}\Big(\mathcal{E}(v + \varepsilon\dot{v}, \sigma) - \mathcal{E}(v, \sigma)\Big),\\ \mathcal{E}'_\sigma(v, \sigma)\dot{\sigma} &:= \lim_{\varepsilon\to 0} \frac{1}{\varepsilon}\Big(\mathcal{E}(v, \sigma + \varepsilon\dot{\sigma}) - \mathcal{E}(v, \sigma)\Big).\end{aligned}$$

To linearize the equation $\mathcal{E}(v, \sigma) = 0$, we use a standard remark in the comparison between partially and fully linearized equations for systems obtained by the change of variables $z = y - \sigma(x)$.

Lemma 3.4. *There holds*

$$\mathcal{E}'_v(v, \sigma)\dot{v} + \mathcal{E}'_\sigma(v, \sigma)\dot{\sigma} = \mathcal{E}'_v(v, \sigma)\Big(\dot{v} - (\partial_z v)\dot{\sigma}\Big). \tag{3.6}$$

Proof. See [2] or [32]. ☐

The identity (3.6) was pointed out by S. Alinhac ([2]) along with the role of what he called “the good unknown” $\dot{u}$ defined by

$$\dot{u} = \dot{v} - (\partial_z v)\dot{\sigma}.$$

Since $\mathcal{E}(v,\sigma)$ is linear with respect to v, we have

$$\mathcal{E}'_v(v,\sigma)\dot{v} = \mathcal{E}(\dot{v},\sigma) = L\dot{v} - \Delta\sigma\partial_z\dot{v},$$

from which we obtain the following formula for the linearized interior equation.

Proposition 3.5. *There holds*

$$(1+|\nabla\sigma|^2)\partial_z^2\dot{u} + \Delta\dot{u} - 2\nabla\sigma\cdot\nabla\partial_z\dot{u} - \Delta\sigma\partial_z\dot{u} = 0,$$

where $\dot{u} := \dot{v} - (\partial_z v)\dot{\sigma}$.

We conclude this part by making two remarks concerning the good unknown of Alinhac.

Remark 3.6. The good unknown $\dot{u} = \dot{v} - (\partial_z v)\dot{\sigma}$ was introduced by Lannes [27] in the analysis of the linearized equations of the Cauchy problem for the water waves. The computations of Lannes play a key role in [22]. We have explained differently the reason why $\dot{u}$ simplifies the computations by means of the general identity (3.6) (compare with the proof of Prop. 4.2 in [27]). We also refer to a very recent paper by Trakhinin ([42]) where the author also uses the good unknown of Alinhac to study the Cauchy problem.

Remark 3.7. A geometrical way to understand the role of the good unknown $\dot{v} - \partial_z v\dot{\sigma}$ is to note that the vector field $D_x := \nabla - \nabla\sigma\partial_z$ commutes with the interior equation (3.2) for v: we have

$$\Big(L - \Delta\sigma\partial_z\Big)D_x v = 0.$$

The previous result can be checked directly. Alternatively, it follows from the identity

$$\Big(L - \Delta\sigma\partial_z\Big)D_x v = (D_x^2 + \partial_z^2)D_x v,$$

and the fact that D_x commutes with ∂_z. This explains why $\dot{u}$ is the natural unknown whenever one solves a free boundary problem by straightening the free boundary.

3.3 Linearized boundary conditions

It turns out that the good unknown $\dot{u}$ is also useful to compute the linearized boundary conditions. Indeed, by differentiating the first boundary condition (3.3), and replacing $\dot{v}$ by $\dot{u} + (\partial_z v)\dot{\sigma}$ we obtain

$$\begin{aligned}(1+|\nabla\sigma|^2)\partial_z\dot{u} - \nabla\sigma\cdot\nabla\dot{u} - (c + \nabla v - \partial_z v\nabla\sigma)\cdot\nabla\dot{\sigma}&\\ + \dot{\sigma}\Big((1+|\nabla\sigma|^2)\partial_z^2 v - \nabla\sigma\cdot\nabla\partial_z v\Big) &= 0.\end{aligned}$$

The interior equation (3.2) for v implies that

$$(1+|\nabla\sigma|^2)\partial_z^2 v - \nabla\sigma\cdot\nabla\partial_z v = -\operatorname{div}\Big(\nabla v - \partial_z v\nabla\sigma\Big).$$

which in turn implies that

$$(1+|\nabla\sigma|^2)\partial_z\dot{u} - \nabla\sigma\cdot\nabla\dot{u} - \operatorname{div}\Big((c+\nabla v - \partial_z v\nabla\sigma)\dot{\sigma}\Big) = 0.$$

With regards to the second boundary condition, we easily find that

$$\mathfrak{a}\dot{\sigma} + \big(c+\nabla v - \partial_z v\nabla\sigma\big)\cdot\nabla\dot{u} = 0,$$

with $\mathfrak{a} := \mu + \big(c+\nabla v - \partial_z v\nabla\sigma\big)\cdot\nabla\partial_z v$.

Hence, we have the following proposition.

Proposition 3.8. *On $\{z=0\}$, the linearized boundary conditions are*

$$\begin{cases} N\dot{u} - \operatorname{div}(V\dot{\sigma}) = 0, \\ \mathfrak{a}\dot{\sigma} + (V\cdot\nabla)\dot{u} = 0, \end{cases} \tag{3.7}$$

where N is the Neumann operator

$$N = (1+|\nabla\sigma|^2)\partial_z - \nabla\sigma\cdot\nabla, \tag{3.8}$$

and

$$V = c+\nabla v - \partial_z v\nabla\sigma, \quad \mathfrak{a} = \mu + V\cdot\nabla\partial_z v.$$

Remark 3.9. On $\{z=0\}$, directly from the definition, we compute

$$V = c + (\nabla\phi)(x,\sigma(x)).$$

With regards to the coefficient $\mathfrak{a}$, we have (cf Lemma 5.4)

$$\mathfrak{a} = -(\partial_y P)(x,\sigma(x)).$$

4 Paralinearization of the Dirichlet to Neumann operator

In this section we prove Theorem 2.12.

4.1 Paradifferential calculus

We start with some basic reminders and a few more technical issues about paradifferential operators.

4.1.1 Notations

We denote by $\widehat{u}$ or $\mathcal{F}u$ the Fourier transform acting on temperate distributions $u \in \mathcal{S}'(\mathbf{R}^d)$, and in particular on periodic distributions. The spectrum of u is the support of $\mathcal{F}u$. Fourier multipliers are defined by the formula

$$p(D_x)u = \mathcal{F}^{-1}\left(p\mathcal{F}u\right),$$

provided that the multiplication by p is defined at least from $\mathcal{S}(\mathbf{R}^d)$ to $\mathcal{S}'(\mathbf{R}^d)$; $p(D_x)$ is the operator associated to the symbol $p(\xi)$.

According to the usual definition, for $\rho \in]0,+\infty[\backslash\mathbf{N}$, we denote by C^ρ the space of bounded functions whose derivatives of order $[\rho]$ are uniformly Hölder continuous with exponent $\rho - [\rho]$.

4.1.2 Paradifferential operators

The paradifferential calculus was introduced by J.-M. Bony [6] (see also [21, 31, 33, 40]). It is a quantization of symbols $a(x,\xi)$, of degree m in ξ and limited regularity in x, to which are associated operators denoted by T_a, of order $\leq m$.

We consider symbols in the following classes.

Definition 4.1. *Given $\rho \geq 0$ and $m \in \mathbf{R}$, $\Gamma^m_\rho(\mathbf{T}^d)$ denotes the space of locally bounded functions $a(x,\xi)$ on $\mathbf{T}^d \times (\mathbf{R}^d\backslash 0)$, which are C^∞ with respect to ξ for $\xi \neq 0$ and such that, for all $\alpha \in \mathbf{N}^d$ and all $\xi \neq 0$, the function $x \mapsto \partial_\xi^\alpha a(x,\xi)$ belongs to $C^\rho(\mathbf{T}^d)$ and there exists a constant C_α such that,*

$$\forall\, |\xi| \geq \frac{1}{2}, \quad \left\| \partial_\xi^\alpha a(\cdot,\xi) \right\|_{C^\rho} \leq C_\alpha (1+|\xi|)^{m-|\alpha|}. \tag{4.1}$$

Remark 4.2. The analysis remains valid if we replace C^ρ by $W^{\rho,\infty}$ for $\rho \in \mathbf{N}$.

Note that we consider symbols $a(x,\xi)$ that need not be smooth for $\xi = 0$ (for instance $a(x,\xi) = |\xi|^m$ with $m \in \mathbf{R}^*$). The main motivation for considering such symbols comes from the principal symbol of the Dirichlet to Neumann operator. As already mentioned, it is known that this symbol is given by

$$\lambda^1_\sigma(x,\xi) := \sqrt{\left(1+|\nabla\sigma(x)|^2\right)|\xi|^2 - (\nabla\sigma(x)\cdot\xi)^2}.$$

If $\sigma \in C^s(\mathbf{T}^d)$ then this symbol belongs to $\Gamma^1_{s-1}(\mathbf{T}^d)$. Of course, this symbol is not C^∞ with respect to $\xi \in \mathbf{R}^d$.

The consideration of the symbol λ_σ also suggests that we shall be led to consider pluri-homogeneous symbols.

Definition 4.3. *Let $\rho \geq 1$, $m \in \mathbf{R}$. The classes $\Sigma_\rho^m(\mathbf{T}^d)$ are defined as the spaces of symbols a such that*

$$a(x,\xi) = \sum_{0 \leq j < \rho} a_{m-j}(x,\xi),$$

where $a_{m-j} \in \Gamma_{\rho-j}^{m-j}(\mathbf{T}^d)$ is homogeneous of degree $m-j$ in ξ, C^∞ in ξ for $\xi \neq 0$ and with regularity $C^{\rho-j}$ in x. We call a_m the principal symbol of a.

The definition of paradifferential operators needs two arbitrary but fixed cutoff functions χ and ψ. Introduce $\chi = \chi(\theta,\eta)$ such that χ is a C^∞ function on $\mathbf{R}^d \times \mathbf{R}^d \setminus 0$, homogeneous of degree 0 and satisfying, for $0 < \varepsilon_1 < \varepsilon_2$ small enough,

$$\begin{aligned} \chi(\theta,\eta) = 1 \quad &\text{if} \quad |\theta| \leq \varepsilon_1 |\eta|, \\ \chi(\theta,\eta) = 0 \quad &\text{if} \quad |\theta| \geq \varepsilon_2 |\eta|. \end{aligned}$$

We also introduce a C^∞ function ψ such that $0 \leq \psi \leq 1$,

$$\psi(\eta) = 0 \quad \text{for} \ |\eta| \leq 1, \qquad \psi(\eta) = 1 \quad \text{for} \ |\eta| \geq 2.$$

Given a symbol $a(x,\xi)$, we then define the paradifferential operator T_a by

$$\widehat{T_a u}(\xi) = (2\pi)^{-d} \int \chi(\xi-\eta,\eta)\widehat{a}(\xi-\eta,\eta)\psi(\eta)\widehat{u}(\eta)\,d\eta, \tag{4.2}$$

where $\widehat{a}(\theta,\xi) = \int e^{-ix\cdot\theta} a(x,\xi)\,dx$ is the Fourier transform of a with respect to the first variable. We call attention to the fact that this notation is not quite standard since u and a are periodic in x. To clarify notations, fix $\mathbf{T}^d = \mathbf{R}^d/L$ for some lattice L. Then we can write (4.2) as

$$\widehat{T_a u}(\xi) = (2\pi)^{-d} \sum_{\eta \in L^*} \chi(\xi-\eta,\eta)\widehat{a}(\xi-\eta,\eta)\psi(\eta)\widehat{u}(\eta).$$

Also, we call attention to the fact that, if $Q(D_x)$ is a Fourier multiplier with symbol $q(\xi)$, then we do not have $Q(D_x) = T_q$, because of the cut-off function ψ. However, this is obviously almost true since we have $Q(D_x) = T_q + R$ where R maps H^t to H^∞ for all $t \in \mathbf{R}$.

Recall the following definition, which is used continually in the sequel.

Definition 4.4. *Let $m \in \mathbf{R}$. An operator T is said of order $\leq m$ if, for all $s \in \mathbf{R}$, it is bounded from H^{s+m} to H^s.*

Theorem 4.5. *Let $m \in \mathbf{R}$. If $a \in \Gamma_0^m(\mathbf{T}^d)$, then T_a is of order $\leq m$.*

We refer to (4.7) below for operator norms estimates.

We next recall the main feature of symbolic calculus, which is a symbolic calculus lemma for composition of paradifferential operators. The basic property, which will be freely used in the sequel, is the following

$$a \in \Gamma_1^m(\mathbf{T}^d), b \in \Gamma_1^{m'}(\mathbf{T}^d) \Rightarrow T_a T_b - T_{ab} \text{ is of order } \leq m + m' - 1.$$

More generally, there is an asymptotic formula for the composition of two such operators, whose main term is the pointwise product of their symbols.

Theorem 4.6. *Let* $m, m' \in \mathbf{R}$. *Consider* $a \in \Gamma_\rho^m(\mathbf{T}^d)$ *and* $b \in \Gamma_\rho^{m'}(\mathbf{T}^d)$ *where* $\rho \in]0, +\infty[$, *and set*

$$a\sharp b(x,\xi) = \sum_{|\alpha|<\rho} \frac{1}{i^\alpha \alpha!} \partial_\xi^\alpha a(x,\xi) \partial_x^\alpha b(x,\xi) \in \sum_{j<\rho} \Gamma_{\rho-j}^{m+m'-j}(\mathbf{T}^d).$$

Then, the operator $T_a T_b - T_{a\sharp b}$ *is of order* $\leq m + m' - \rho$.

Proofs of these two theorems can be found in the references cited above. Clearly, the fact that we consider symbols which are periodic in x does not change the analysis. Also, as noted in [31], the fact that we consider symbols which are not smooth at the origin $\xi = 0$ is not a problem. Here, since we added the extra function ψ in the definition (4.2), following the original definition in [6], the argument is elementary: if $a \in \Gamma_\rho^m(\mathbf{T}^d)$, then $\psi(\xi)a(x,\xi)$ belongs to the usual class of symbols.

4.1.3 Paraproducts

If $a = a(x)$ is a function of x only, the paradifferential operator T_a is a called a paraproduct. For easy reference, we recall a few results about paraproducts.

We already know from Theorem 4.5 that, if $\beta > d/2$ and $b \in H^\beta(\mathbf{T}^d) \subset C^0(\mathbf{T}^d)$, then T_b is of order ≤ 0 (note that this holds true if we only assume that $b \in L^\infty$). An interesting point is that one can extend the analysis to the case where $b \in H^\beta(\mathbf{T}^d)$ with $\beta < d/2$.

Lemma 4.7. *For all* $\alpha \in \mathbf{R}$ *and all* $\beta < d/2$,

$$a \in H^\alpha(\mathbf{T}^d),\ b \in H^\beta(\mathbf{T}^d) \quad \Rightarrow \quad T_b a \in H^{\alpha+\beta-\frac{d}{2}}(\mathbf{T}^d).$$

We also have the two following key lemmas about paralinearization.

Lemma 4.8. *For* $a \in H^\alpha(\mathbf{T}^d)$ *with* $\alpha > d/2$ *and* $F \in C^\infty$,

$$F(a) - T_{F'(a)}a \in H^{2\alpha-\frac{d}{2}}(\mathbf{T}^d). \tag{4.3}$$

For all $\alpha, \beta \in \mathbf{R}$ *such that* $\alpha + \beta > 0$,

$$a \in H^\alpha(\mathbf{T}^d), b \in H^\beta(\mathbf{T}^d) \ \Rightarrow\ ab - T_a b - T_b a \in H^{\alpha+\beta-\frac{d}{2}}(\mathbf{T}^d). \tag{4.4}$$

There is also one straightforward consequence of Theorem 4.6 that will be used below.

Lemma 4.9. *Assume that* $t > d/2$ *is such that* $t - d/2 \notin \mathbf{N}$. *If* $a \in H^t$ *and* $b \in H^t$, *then*

$$T_a T_b - T_{ab} \text{ is of order } \leq -\left(t - \frac{d}{2}\right).$$

4.1.4 Maximal elliptic regularity

In this paragraph, we are concerned with scalar elliptic evolution equations of the form

$$\partial_z u + T_a u = T_b u + f \qquad (z \in [-1,0], x \in \mathbf{T}^d),$$

where $b \in \Gamma^0_0(\mathbf{T}^d)$ and $a \in \Gamma^1_2(\mathbf{T}^d)$ is a first-order elliptic symbol with positive real part and with regularity C^2 in x.

With regards to further applications, we make the somewhat unconventional choice to take the Cauchy datum on $z = -1$. Recall that we denote by $C^0([-1,0]; H^m(\mathbf{T}^d))$ the space of continuous functions in $z \in [-1,0]$ with values in $H^m(\mathbf{T}^d)$. We prove that, if $f \in C^0([-1,0]; H^s(\mathbf{T}^d))$, then $u(0) \in H^{s+1-\varepsilon}(\mathbf{T}^d)$ for any $\varepsilon > 0$ (where $u(0)(x) = u|_{z=0} = u(x,0)$). This corresponds the usual gain of 1/2 derivative for the Poisson kernel. This result is not new. Yet, for lack of a reference, we include a detailed analysis.

Proposition 4.10. *Let* $r \in [0,1[$, $a(x,\xi) \in \Gamma^1_{1+r}(\mathbf{T}^d)$ *and* $b(x,\xi) \in \Gamma^0_0(\mathbf{T}^d)$. *Assume that there exists* $c > 0$ *such that*

$$\forall (x,\xi) \in \mathbf{T}^d \times \mathbf{R}^d, \quad \operatorname{Re} a(x,\xi) \geq c\,|\xi|\,.$$

If $u \in C^1([-1,0]; H^{-\infty}(\mathbf{T}^d))$ *solves the elliptic evolution equation*

$$\partial_z u + T_a u = T_b u + f,$$

with $f \in C^0([-1,0]; H^s(\mathbf{T}^d))$ *for some* $s \in \mathbf{R}$, *then*

$$u(0) \in H^{s+r}(\mathbf{T}^d).$$

Proof. The following proof gives the stronger conclusion that u is continuous in $z \in]-1,0]$ with values in $H^{s+r}(\mathbf{T}^d)$. Therefore, by an elementary induction argument, we can assume without loss of generality that $b = 0$ and $u \in C^0([-1,0]; H^s(\mathbf{T}^d))$. In addition one can assume that $u(t,x,z) = 0$ for $z \leq -1/2$.

Introduce the symbol

$$\begin{aligned} e(z;x,\xi) &:= e_0(z;x,\xi) + e_{-1}(z;x,\xi) \\ &= \exp\left(za(x,\xi)\right) + \exp\left(za(x,\xi)\right)\frac{z^2}{2i}\partial_\xi a(x,\xi)\cdot\partial_x a(x,\xi), \end{aligned}$$

so that $e(0;x,\xi)=1$ and

$$\partial_z e = e_0 a + e_{-1} a + \frac{1}{i}\partial_\xi e_0 \cdot \partial_x a. \tag{4.5}$$

According to our assumption that $\operatorname{Re} a \geq c\,|\xi|$, we have the simple estimates

$$(z\,|\xi|)^\ell \exp\left(za(x,\xi)\right) \leq C_\ell.$$

Therefore

$$e_0 \in C^0([-1,0];\Gamma^0_{1+r}(\mathbf{T}^d)), \quad e_{-1} \in C^0([-1,0];\Gamma^{-1}_r(\mathbf{T}^d)).$$

According to (4.5) and Theorem 4.6, then, $T_{\partial_z e} - T_e T_a$ is of order $\leq -r$. Write

$$\partial_z\left(T_e u\right) = T_e f + F,$$

with $F \in C^0([-1,0];H^{s+r}(\mathbf{T}^d))$ and integrate on $[-1,0]$ to obtain

$$T_1 u(0) = \int_{-1}^0 F(y)\,dy + \int_{-1}^0 (T_e f)(y)\,dy. \tag{4.6}$$

Since $F \in C^0([-1,0];H^{s+r}(\mathbf{T}^d))$, the first term in the right-hand side belongs to $H^{s+r}(\mathbf{T}^d)$. Moreover $u(0) - T_1 u(0) \in H^{+\infty}(\mathbf{T}^d)$ and hence it remains only to study the second term in the right-hand side of (4.6). Set

$$\widetilde{u}(0) := \int_{-1}^0 (T_e f)(y)\,dy.$$

To prove that $\widetilde{u}(0)$ belongs to $H^{s+r}(\mathbf{T}^d)$, the key observation is that, since $\operatorname{Re} a \geq c\,|\xi|$, the family

$$\left\{\, (|y|\,|\xi|)^r e(y;x,\xi) \mid -1 \leq y \leq 0 \,\right\}$$

is bounded in $\Gamma^r_0(\mathbf{T}^d)$. Once this is granted, we use the following result (see [31]) about operator norms estimates. Given $s \in \mathbf{R}$ and $m \in \mathbf{R}$, there is a constant C such that, for all $\tau \in \Gamma^m_0(\mathbf{T}^d)$ and all $v \in H^{s+m}(\mathbf{T}^d)$,

$$\left\lVert T_\tau v\right\rVert_{H^s} \leq C \sup_{|\alpha| \leq \frac{d}{2}+1} \sup_{|\xi| \geq 1/2} \left\lVert (1+|\xi|)^{|\alpha|-m} \partial_\xi^\alpha \tau(\cdot,\xi)\right\rVert_{C^0(\mathbf{T}^d)} \left\lVert v\right\rVert_{H^{s+m}}. \tag{4.7}$$

This estimate implies that there is a constant K such that, for all $-1 \leq y \leq 0$ and all $v \in H^s(\mathbf{T}^d)$,

$$\left\lVert (|y|\,|D_x|)^r (T_e v)\right\rVert_{H^s} \leq K \left\lVert v\right\rVert_{H^s}.$$

By applying this result we obtain that there is a constant K such that, for all $y \in [-1,0[$,

$$\left\lVert (T_e f)(y)\right\rVert_{H^{s+r}} \leq \frac{K}{|y|^r} \left\lVert f(y)\right\rVert_{H^s}.$$

Since $|y|^{-r} \in L^1(]-1,0[)$, this implies that $\widetilde{u}(0) \in H^{s+r}(\mathbf{T}^d)$. This completes the proof. □

4.2 Paralinearization of the interior equation

With these preliminaries established, we start the proof of Theorem 2.12. From now on we fix $s \geq 3 + d/2$ such that $s - d/2 \notin \mathbf{N}$, $\sigma \in H^s(\mathbf{T}^d)$ and $\psi \in H^s(\mathbf{T}^d)$. As already explained, we use the change of variables $z = y - \sigma(x)$ to reduce the problem to the fixed domain

$$\{(x, z) \in \mathbf{T}^d \times \mathbf{R} \, : \, z < 0\}.$$

That is, we set

$$v(x, z) = \varphi(x, z + \sigma(x)),$$

which satisfies

$$(1 + |\nabla\sigma|^2)\partial_z^2 v + \Delta v - 2\nabla\sigma \cdot \nabla\partial_z v - \partial_z v \Delta\sigma = 0 \quad \text{in } \{z < 0\}, \tag{4.8}$$

and the following boundary condition

$$(1 + |\nabla\sigma|^2)\partial_z v - \nabla\sigma \cdot \nabla v = G(\sigma)\psi \quad \text{on } \{z = 0\}. \tag{4.9}$$

Henceforth we denote simply by $C^0(H^r)$ the space of continuous functions in $z \in [-1, 0]$ with values in $H^r(\mathbf{T}^d)$. By assumption, we have

$$v \in C^0(H^s), \quad \partial_z v \in C^0(H^{s-1}). \tag{4.10}$$

There is one observation that will be useful below.

Lemma 4.11. *For $k = 2, 3$,*

$$\partial_z^k v \in C^0(H^{s-k}). \tag{4.11}$$

Proof. This follows directly from the equation (4.8), the assumption (4.10) and the classical rule of product in Sobolev spaces which we recall here. For $t_1, t_2 \in \mathbf{R}$, the product maps $H^{t_1}(\mathbf{T}^d) \times H^{t_2}(\mathbf{T}^d)$ to $H^t(\mathbf{T}^d)$ whenever

$$t_1 + t_2 \geq 0, \quad t \leq \min\{t_1, t_2\} \quad \text{and} \quad t \leq t_1 + t_2 - d/2,$$

with the third inequality strict if t_1 or t_2 or $-t$ is equal to $d/2$ (cf [21]). ☐

We use the tangential paradifferential calculus, that is the paradifferential quantization T_a of symbols $a(z, x, \xi)$ depending on the phase space variables $(x, \xi) \in T^*\mathbf{T}^d$ and possibly on the parameter $z \in [-1, 0]$. Based on the discussion earlier, to paralinearize the interior equation (4.8), it is natural to introduce what we call the *good unknown*

$$u := v - T_{\partial_z v}\, \sigma. \tag{4.12}$$

(A word of caution: $\psi - T_{\mathfrak{b}}\sigma$, which is what we called the good unknown in the introduction, corresponds to the trace on $\{z = 0\}$ of u.)

The following result is the key technical point.

Proposition 4.12. *The good unknown* $u = v - T_{\partial_z v}\,\sigma$ *satisfies the paradifferential equation*

$$T_{(1+|\nabla\sigma|^2)}\partial_z^2 u - 2T_{\nabla\sigma}\cdot\nabla\partial_z u + \Delta u - T_{\Delta\sigma}\partial_z u = f_0, \tag{4.13}$$

where

$$f_0 \in C^0(H^{2s-3-\frac{d}{2}}).$$

Proof. Introduce the notations

$$E := (1+|\nabla\sigma|^2)\partial_z^2 - 2\nabla\sigma\cdot\nabla\partial_z + \Delta - \Delta\sigma\partial_z$$

and

$$P := T_{(1+|\nabla\sigma|^2)}\partial_z^2 - 2T_{\nabla\sigma}\cdot\nabla\partial_z + \Delta - T_{\Delta\sigma}\partial_z.$$

We begin by proving that v satisfies

$$Ev - Pv - T_{\partial_z^2 v}\,|\nabla\sigma|^2 + 2T_{\nabla\partial_z v}\nabla\sigma + T_{\partial_z v}\Delta\sigma \in C^0(H^{2s-3-\frac{d}{2}}). \tag{4.14}$$

This follows from the paralinearization lemma 4.8, which implies that

$$\begin{aligned}
&\nabla\sigma\cdot\nabla\partial_z v - T_{\nabla\sigma}\cdot\nabla\partial_z v - T_{\nabla\partial_z v}\cdot\nabla\sigma \in C^0(H^{2s-3-\frac{d}{2}}),\\
&|\nabla\sigma|^2\partial_z^2 v - T_{|\nabla\sigma|^2}\partial_z^2 v - T_{\partial_z^2 v}|\nabla\sigma|^2 \in C^0(H^{2s-3-\frac{d}{2}}),\\
&\partial_z v\Delta_x\sigma - T_{\partial_z v}\Delta\sigma - T_{\Delta\sigma}\partial_z v \in C^0(H^{2s-3-\frac{d}{2}}).
\end{aligned}$$

We next substitute $v = u + T_{\partial_z v}\sigma$ in (4.14). Directly from the definition of u, we obtain

$$\begin{aligned}
\partial_z^2 u &= \partial_z^2 v - T_{\partial_z^3 v}\sigma,\\
\nabla\partial_z u &= \nabla\partial_z v - T_{\partial_z^2 v}\nabla\sigma - T_{\nabla\partial_z^2 v}\sigma,\\
\Delta u &= \Delta v - T_{\partial_z v}\Delta\sigma + 2T_{\nabla\partial_z v}\cdot\nabla\sigma - T_{\Delta\partial_z v}\sigma.
\end{aligned}$$

Since

$$(1+|\nabla\sigma|^2)\partial_z^2 v - 2\nabla\sigma\cdot\nabla\partial_z v + \Delta v - \Delta\sigma\partial_z v = 0,$$

by using Lemma 4.9 and (4.11) we obtain the key cancelation

$$T_{(1+|\nabla\sigma|^2)}T_{\partial_z^3 v}\sigma - 2T_{\nabla\sigma}T_{\nabla\partial_z^2 v}\sigma + T_{\Delta\partial_z v}\sigma - T_{\partial_z^2 v\Delta\sigma}\sigma \in C^0(H^{2s-3-\frac{d}{2}}). \tag{4.15}$$

Then,

$$Pu - Pv + T_{\partial_z v}\Delta\sigma - \Big(2T_{\nabla\sigma}\cdot T_{\partial_z^2 v}\nabla\sigma - 2T_{\nabla\partial_z v}\nabla\sigma\Big) \in C^0(H^{2s-3-\frac{d}{2}}),$$

so that

$$Ev - Pu + \Big(2T_{\nabla\sigma}\cdot T_{\partial_z^2 v}\nabla\sigma - T_{\partial_z^2 v}\,|\nabla\sigma|^2\Big) \in C^0(H^{2s-3-\frac{d}{2}}),$$

The symbolic calculus implies that

$$2T_{\partial_z^2 v}T_{\nabla\sigma}\cdot\nabla\sigma - T_{\partial_z^2 v}\,|\nabla\sigma|^2 \in C^0(H^{2s-2-\frac{d}{2}}).$$

Which concludes the proof. $\square$

4.3 Reduction to the boundary

As already mentioned, it is known that, if σ is a C^∞ given function, then the Dirichlet to Neumann operator $G(\sigma)$ is a classical pseudo-differential operator. The proof of this result is based on elliptic factorization. We here perform this elliptic factorization for the equation for the good unknown. We next apply this lemma to determine the normal derivatives of u at the boundary in terms of tangential derivatives.

We have just proved that

$$T_{(1+|\nabla\sigma|^2)}\partial_z^2 u - 2T_{\nabla\sigma}\cdot\nabla\partial_z u + \Delta u - T_{\Delta\sigma}\partial_z u = f_0 \in C^0(H^{2s-3-\frac{d}{2}}). \tag{4.16}$$

Set

$$b = \frac{1}{1+|\nabla\sigma|^2}.$$

Since $b \in H^{s-1}(\mathbf{T}^d)$, by applying Lemma 4.9, we find that one can equivalently rewrite equation (4.16) as

$$\partial_z^2 u - 2T_{b\nabla\sigma}\cdot\nabla\partial_z u + T_b\Delta u - T_{b\Delta\sigma}\partial_z u = f_1 \in C^0(H^{2s-3-\frac{d}{2}}). \tag{4.17}$$

Following the strategy in [39], we shall perform a full decoupling into a forward and a backward elliptic evolution equations. Recall that the classes $\Sigma^m_\rho(\mathbf{T}^d)$ have been defined in §4.1.2.

Lemma 4.13. *There exist two symbols $a, A \in \Sigma^1_{s-1-d/2}(\mathbf{T}^d)$ such that,*

$$(\partial_z - T_a)(\partial_z - T_A)u = f \in C^0(H^{2s-3-\frac{d}{2}}). \tag{4.18}$$

Proof. We seek a and A in the form

$$a(x,\xi) = \sum_{0\le j<t} a_{1-j}(x,\xi), \qquad A(x,\xi) = \sum_{0\le j<t} A_{1-j}(x,\xi), \tag{4.19}$$

where

$$t := s - 3 - d/2,$$

and

$$a_m, A_m \in \Gamma^m_{t+1+m} \qquad (-t < m \le 1).$$

We want to solve the system

$$\begin{aligned} a\sharp A &:= \sum a_k \sharp A_\ell = -b\,|\xi|^2 + r(x,\xi),\\ a + A &= \sum a_k + A_k = 2b(i\nabla\sigma\cdot\xi) + b\Delta\sigma, \end{aligned} \tag{4.20}$$

for some admissible remainder $r \in \Gamma^{-t}_0(\mathbf{T}^d)$. Note that the notation $\sharp$, as given in Theorem 4.6 depends on the regularity of the symbols. To clarify notations, we explicitly set

$$a\sharp A := \sum\sum\sum_{|\alpha|<t+\min\{k,\ell\}} \frac{1}{i^\alpha \alpha!}\partial_\xi^\alpha a_k \partial_x^\alpha A_\ell.$$

Assume that we have defined a and A such that (4.20) is satisfied, and let us then prove the desired result (4.18). For $r \in [1, +\infty)$, use the notation

$$a \sharp_r b(x,\xi) = \sum_{|\alpha| < r} \frac{1}{i^\alpha \alpha!} \partial_\xi^\alpha a(x,\xi) \partial_x^\alpha b(x,\xi).$$

Then, Theorem 4.6 implies that

$$\begin{aligned}
&T_{a_1} T_{A_1} - T_{a_1 \sharp_{s-1} A_1} \quad \text{is of order } \le 1 + 1 - (s-1) - \frac{d}{2} = -t,\\
&T_{a_1} T_{A_0} - T_{a_1 \sharp_{s-2} A_0} \quad \text{is of order } \le 1 + 0 - (s-2) - \frac{d}{2} = -t,\\
&T_{a_0} T_{A_1} - T_{a_0 \sharp_{s-2} A_1} \quad \text{is of order } \le 0 + 1 - (s-2) - \frac{d}{2} = -t,
\end{aligned}$$

and, for $-t \le k, \ell \le 0$,

$$T_{a_k} T_{A_\ell} - T_{a_k \sharp_{s-2+\min\{k,\ell\}} A_\ell} \text{ is of order } \le k + \ell - (s - 2 + \min\{k,\ell\}) - \frac{d}{2} \le -t - 1.$$

Consequently, $T_a T_A - T_{a \sharp A}$ is of order $\le -t$. The first equation in (4.20) then implies that

$$T_a T_A u - b \Delta u \in C^0(H^{s+t}),$$

while the second equation directly gives

$$\partial_z T_A + T_a \partial_z u - \big(2 T_{b \nabla \sigma} \cdot \nabla \partial_z u - T_{b \Delta \sigma} \partial_z u \big) \in C^0(H^{s+t}).$$

We thus obtain the desired result (4.18) from (4.17).

To define the symbols a_m, A_m, we remark first that $a \sharp A = \tau + \omega$ with $\omega \in \Gamma_0^{3-s}(\mathbf{T}^d)$ and

$$\tau := \sum \sum \sum_{|\alpha| < s - 3 + k + \ell} \frac{1}{i^\alpha \alpha!} \partial_\xi^\alpha a_k \partial_x^\alpha A_\ell. \tag{4.21}$$

We then write $\tau = \sum \tau_m$ where τ_m is of order m. Together with the second equation in (4.20), this yields a cascade of equations that allows to determine a_m and A_m by induction.

Namely, we determine a and A as follows. We first solve the principal system:

$$\begin{aligned}
a_1 A_1 &= -b \left| \xi \right|^2,\\
a_1 + A_1 &= 2ib \nabla \sigma \cdot \xi,
\end{aligned}$$

by setting

$$\begin{aligned}
a_1(x,\xi) &= ib \nabla \sigma \cdot \xi - \sqrt{b |\xi|^2 - (b \nabla \sigma \cdot \xi)^2},\\
A_1(x,\xi) &= ib \nabla \sigma \cdot \xi + \sqrt{b |\xi|^2 - (b \nabla \sigma \cdot \xi)^2}.
\end{aligned}$$

Note that $b|\xi|^2 - (b\nabla\sigma \cdot \xi)^2 \geq b^2|\xi|^2$ so that the symbols a_1, A_1 are well defined and belong to $\Gamma^1_{s-1-d/2}(\mathbf{T}^d)$.

We next solve the sub-principal system

$$\begin{aligned}&a_0 A_1 + a_1 A_0 + \frac{1}{i}\partial_\xi a_1 \partial_x A_1 = 0,\\&a_0 + A_0 = b\Delta\sigma.\end{aligned}$$

It is found that

$$a_0 = \frac{i\partial_\xi a_1 \cdot \partial_x A_1 - b\Delta\sigma a_1}{A_1 - a_1}, \quad A_0 = \frac{i\partial_\xi a_1 \cdot \partial_x A_1 - b\Delta\sigma A_1}{a_1 - A_1}.$$

Once the principal and sub-principal symbols have been defined, one can define the other symbols by induction. By induction, for $-t+1 \leq m \leq 0$, suppose that $a_1, \dots, a_m$ and $A_1, \dots, A_m$ have been determined. Then define a_{m-1} and A_{m-1} by

$$A_{m-1} = -a_{m-1},$$

and

$$a_{m-1} = \frac{1}{a_1 - A_1}\sum\sum\sum \frac{1}{i^\alpha \alpha!}\partial_\xi^\alpha a_k \partial_x^\alpha A_\ell$$

where the sum is over all triple $(k, \ell, \alpha) \in \mathbf{Z} \times \mathbf{Z} \times \mathbf{N}^d$ such that

$$m \leq k \leq 1, \quad m \leq \ell \leq 1, \quad |\alpha| = k + \ell - m.$$

By definition, one has $a_m, A_m \in \Gamma^m_{t+1+m}$ for $-t+1 < m \leq 0$. Also, we obtain that $\tau = -b\,|\xi|^2$ and $a + A = 2b(i\nabla\sigma \cdot \xi) + b\Delta\sigma$.

This completes the proof. □

We now complete the reduction to the boundary. As a consequence of the precise parametrix exhibited in Lemma 4.13, we describe the boundary value of $\partial_z u$ up to an error in $H^{2s-2-\frac{d}{2}-0}(\mathbf{T}^d)$.

Corollary 4.14. *Let $\varepsilon > 0$. On the boundary $\{z = 0\}$, there holds*

$$(\partial_z u - T_A u)|_{z=0} \in H^{2s-2-\frac{d}{2}-\varepsilon}(\mathbf{T}^d), \tag{4.22}$$

where A is given by Lemma 4.13.

Proof. Introduce $w := (\partial_z - T_A)u$ and write $a = a_1 + \widetilde{a}$ where $a_1 \in \Gamma^1_2(\mathbf{T}^d)$ is the principal symbol of a and $\widetilde{a} \in \Gamma^0_0(\mathbf{T}^d)$. Then w satisfies

$$\partial_z w - T_{a_1} w = T_{\widetilde{a}} w + f.$$

Since $f \in C^0(H^{2s-3-\frac{d}{2}})$, and since $\operatorname{Re} a_1 \leq -K\,|\xi|$, Proposition 4.10 applied with $r = 1 - \varepsilon$ implies that

$$(\partial_z u - T_A u)|_{z=0} = w(0) \in H^{2s-2-\frac{d}{2}-\varepsilon}(\mathbf{T}^d).$$

□

4.4 Paralinearization of the Neumann boundary condition

We now conclude the proof of Theorem 2.12. Recall that, by definition,

$$G(\sigma)\psi = (1+|\nabla\sigma|^2)\partial_z v - \nabla\sigma\cdot\nabla v|_{z=0}.$$

As before, on $\{z=0\}$ we find that

$$T_{(1+|\nabla\sigma|^2)}\partial_z v + 2T_{\partial_z v\nabla\sigma}\cdot\nabla\sigma - T_{\nabla\sigma}\cdot\nabla v - T_{\nabla v}\cdot\nabla\sigma \in H^{2s-2-\frac{d}{2}}(\mathbf{T}^d).$$

We next translate this equation to the good unknown $u = v - T_{\partial_z v}\sigma$. It is found that

$$T_{(1+|\nabla\sigma|^2)}\partial_z u - T_{\nabla\sigma}\cdot\nabla u - T_{\nabla v-\partial_z v\nabla\sigma}\cdot\nabla\sigma + T_\alpha\sigma \in H^{2s-2-\frac{d}{2}}(\mathbf{T}^d),$$

with

$$\alpha = (1+|\nabla\sigma|^2)\partial_z^2 v - \nabla\sigma\cdot\nabla\partial_z v.$$

The interior equation for v implies that

$$\alpha = -\operatorname{div}(\nabla v - \partial_z v\nabla\sigma),$$

so that

$$T_{(1+|\nabla\sigma|^2)}\partial_z u - T_{\nabla\sigma}\cdot\nabla u - T_{\nabla v-\partial_z v\nabla\sigma}\cdot\nabla\sigma - T_{\operatorname{div}(\nabla v-\partial_z v\nabla\sigma)}\sigma \in H^{2s-2-\frac{d}{2}}. \tag{4.23}$$

Furthermore, Corollary 4.14 implies that

$$T_{(1+|\nabla\sigma|^2)}\partial_z u - T_{\nabla\sigma}\cdot\nabla u = T_{\lambda_\sigma}u + R, \tag{4.24}$$

with $R\in H^{2s-2-\frac{d}{2}-\varepsilon}(\mathbf{T}^d)$ and

$$\lambda_\sigma = (1+|\nabla\sigma|^2)A - i\nabla\sigma\cdot\xi.$$

In particular, $\lambda_\sigma \in \Sigma^1_{s-1-d/2}(\mathbf{T}^d)$ is a complex-valued elliptic symbol of degree 1, with principal symbol

$$\lambda_\sigma^1(x,\xi) = \sqrt{(1+|\nabla\sigma(x)|^2)|\xi|^2 - (\nabla\sigma(x)\cdot\xi)^2}.$$

By combining (4.23) and (4.24), we conclude the proof of Theorem 2.12.

5 Regularity of diamond waves

In this section, we prove Theorem 2.5, which is better formulated as follows.

Theorem 5.1. *There exist three real-valued functions ν,κ_0,κ_1 defined on $D^{12}(\mathbf{T}^2)$ such that, for all $\omega=(\mu,\sigma,\psi)\in D^s(\mathbf{T}^2)$ with $s\geq 12$,*

i) *if there exist* $\delta \in [0,1[$ *and* $N \in \mathbf{N}^*$ *such that*

$$\left| k_2 - \left(\nu(\omega) k_1^2 + \kappa_0(\omega) + \frac{\kappa_1(\omega)}{k_1^2} \right) \right| \geq \frac{1}{k_1^{2+\delta}},$$

for all $(k_1, k_2) \in \mathbf{N}^2$ *with* $k_1 \geq N$, *then*

$$(\sigma, \psi) \in H^{s+\frac{1-\delta}{2}}(\mathbf{T}^2),$$

and hence $(\sigma, \psi) \in C^\infty(\mathbf{T}^2)$ *by an immediate induction argument.*

ii) $\nu(\omega) \geq 0$ *and there holds the estimate*

$$\left| \nu(\omega) - \frac{1}{\mu} \right| + \left| \kappa_0(\omega) - \kappa_0(\mu, 0, 0) \right| + \left| \kappa_1(\omega) - \kappa_1(\mu, 0, 0) \right| \\ \leq C \left(\|(\sigma, \psi)\|_{H^{12}} + \mu + \frac{1}{\mu} \right) \|(\sigma, \psi)\|_{H^{12}}^2 ,$$

for some non-decreasing function C *independent of* (μ, σ, ψ).

We shall define explicitly the coefficients ν, κ_0, κ_1. The proof of the estimate is left to the reader.

5.1 Paralinearization of the full system

From now on, we fix $\ell > 0$ and $s \geq 12$ and consider a given diamond wave $(\mu, \sigma, \psi) \in D^s(\mathbf{T}^2)$. Recall that the system reads

$$\begin{cases} G(\sigma)\psi - c \cdot \nabla \sigma = 0, \\ \mu \sigma + c \cdot \nabla \psi + \dfrac{1}{2} |\nabla \psi|^2 - \dfrac{1}{2} \dfrac{\left(\nabla \sigma \cdot (\nabla \psi + c) \right)^2}{1 + |\nabla \sigma|^2} = 0, \end{cases} \tag{5.1}$$

where $c = (1, 0)$ so that $c \cdot \nabla = \partial_{x_1}$. In analogy with the previous section, we introduce the coefficient

$$\mathfrak{b} := \frac{\nabla \sigma \cdot (c + \nabla \psi)}{1 + |\nabla \sigma|^2},$$

and what we call the good unknown

$$u := \psi - T_{\mathfrak{b}} \sigma.$$

A word of caution: this corresponds to the trace on $\{z = 0\}$ of what we called the good unknown (also denoted by u) in the previous section.

The first main step is to paralinearize System (5.1).

Proposition 5.2. *The good unknown* $u = \psi - T_{\mathfrak{b}}\sigma$ *and* σ *satisfy*

$$T_{\lambda_\sigma} u - T_V \cdot \nabla\sigma - T_{\operatorname{div} V}\sigma = f_1 \in H^{2s-5}(\mathbf{T}^2), \tag{5.2}$$

$$T_{\mathfrak{a}}\sigma + T_V \cdot \nabla u = f_2 \in H^{2s-3}(\mathbf{T}^2), \tag{5.3}$$

where the symbol $\lambda_\sigma = \lambda_\sigma(x,\xi) \in \Sigma^1_{s-2}(\mathbf{T}^2)$ *is as given by Theorem 2.12. The coefficient* $\mathfrak{a} = \mathfrak{a}(x) \in \mathbf{R}$ *and the vector field* $V = V(x) \in \mathbf{R}^2$ *are given by*

$$V := c + \nabla\psi - \mathfrak{b}\nabla\sigma, \qquad \mathfrak{a} := \mu + V \cdot \nabla\mathfrak{b}.$$

Remark 5.3. The Sobolev embedding gives $\lambda_\sigma \in \Sigma^1_{s-2}(\mathbf{T}^2)$ if and only if $s \notin \mathbf{N}$. For $s \in \mathbf{N}$ we only have $\lambda_\sigma \in \Sigma^1_{s-2-\varepsilon}(\mathbf{T}^2)$ for all $\varepsilon > 0$. Since this changes nothing in the following analysis, we allow ourself to write abusively $\lambda_\sigma \in \Sigma^1_{s-2}(\mathbf{T}^2)$ for all $s \geq 12$.

Proof. The main part of the result, which is (5.2), follows directly from Theorem 2.12 and the regularity result in Remark 2.13. The proof of (5.3) is easier. Indeed, note that for

$$F(a,b) = \frac{1}{2}\frac{(a\cdot b)^2}{1+|a|^2},$$

there holds

$$\partial_b F = \frac{(a\cdot b)}{1+|a|^2}a, \quad \partial_a F = \frac{(a\cdot b)}{1+|a|^2}\Big(b - \frac{(a\cdot b)}{1+|a|^2}a\Big).$$

Using these identities for $a = \nabla\sigma$ and $b = c + \nabla\psi$, the paralinearization lemma (i.e. Lemma 4.8) implies that

$$\mu\sigma + T_V \cdot \nabla\psi - T_{V\mathfrak{b}} \cdot \nabla\sigma \in H^{2s-3}(\mathbf{T}^2).$$

Since $s - 1 > d/2$, the product rule in Sobolev spaces successively implies that

$$\mathfrak{b} = \frac{\nabla\sigma \cdot (c + \nabla\psi)}{1 + |\nabla\sigma|^2} \in H^{s-1}(\mathbf{T}^2), \quad V = c + \nabla\psi - \mathfrak{b}\nabla\sigma \in H^{s-1}(\mathbf{T}^2).$$

Then we use Lemma 4.9 (applied with $t = s-1$), which implies the following:

$$T_{V\mathfrak{b}} \cdot \nabla\sigma - T_V \cdot \nabla(T_{\mathfrak{b}}\sigma) + T_V \cdot T_{\nabla\mathfrak{b}}\sigma = \big(T_{V\mathfrak{b}} - T_V T_{\mathfrak{b}}\big) \cdot \nabla\sigma \in H^{2s-3}(\mathbf{T}^2).$$

Similarly, Lemma 4.9 applied with $t = s - 2$ implies that

$$T_V \cdot T_{\nabla\mathfrak{b}}\sigma - T_{V\cdot\nabla\mathfrak{b}}\sigma \in H^{2s-3}(\mathbf{T}^2).$$

As a corollary, with $\mathfrak{a} = \mu + V \cdot \nabla\mathfrak{b}$, there holds

$$T_{\mathfrak{a}}\sigma + T_V \cdot \nabla u \in H^{2s-3}(\mathbf{T}^2).$$

This completes the proof. □

5.2 The Taylor sign condition

Let ϕ be the harmonic extension of ψ as defined in §2.1, so that

$$\begin{cases} \partial_y^2\phi + \Delta\phi = 0 & \text{in } \Omega, \\ \partial_y\phi - \nabla\sigma\cdot\nabla\phi - c\cdot\nabla\sigma = 0 & \text{on } \partial\Omega, \\ \mu\sigma + \frac{1}{2}\left|\nabla\phi\right|^2 + \frac{1}{2}(\partial_y\phi)^2 + c\cdot\nabla\phi = 0 & \text{on } \partial\Omega, \\ (\nabla\phi, \partial_y\phi) \to (0,0) & \text{as } y\to-\infty, \end{cases} \tag{5.4}$$

where $\Omega = \{\, (x,y) \in \mathbf{R}^2\times\mathbf{R} \,|\, y < \sigma(x)\,\}$. Define the pressure by

$$P(x,y) := -\mu y - \frac{1}{2}|\nabla\phi(x,y)|^2 - \frac{1}{2}(\partial_y\phi(x,y))^2 - c\cdot\nabla\phi(x,y).$$

The following result gives the coefficient $\mathfrak{a}$ (which appeared in Proposition 5.2) in terms of the pressure P.

Lemma 5.4. *There holds* $\mathfrak{a}(x) = -(\partial_y P)(x,\sigma(x))$.

Proof. We have

$$\mathfrak{a}(x) = \mu + (c + (\nabla\phi)(x,\sigma(x)))\cdot\nabla\big((\partial_y\phi)(x,\sigma(x))\big).$$

This yields

$$\mathfrak{a}(x) = \mu + \Big(\partial_y\Big(\frac{1}{2}|\nabla\phi|^2 + c\cdot\nabla\phi\Big) + (c+\nabla\phi)\cdot\nabla\sigma\partial_y^2\phi\Big)(x,\sigma(x)).$$

The Neumann condition $\partial_y\phi - \nabla\sigma\cdot\nabla\phi - c\cdot\nabla\sigma = 0$ implies that

$$\mathfrak{a}(x) = \partial_y\Big(\mu y + \frac{1}{2}|\nabla\phi|^2 + \frac{1}{2}(\partial_y\phi)^2 + c\cdot\nabla\phi\Big)(x,\sigma(x)) = -(\partial_y P)(x,\sigma(x)),$$

which concludes the proof. □

The Taylor sign condition is the physical assumption that the normal derivative of the pressure in the flow at the free surface is negative. The equation

$$\partial_y\phi - \nabla\sigma\cdot\nabla\phi - c\cdot\nabla\phi = 0,$$

implies that $\partial_n P = \partial_y P$ at the free surface. Therefore, the Taylor sign condition reads

$$\forall x\in\mathbf{T}^2, \quad (\partial_y P)(x,\sigma(x)) < 0. \tag{5.5}$$

It is easily proved that this property is satisfied under a smallness assumption (see [22]). Indeed, if $\left\|(\sigma,\psi)\right\|_{C^2} = O(\varepsilon)$, then

$$\left\|(\partial_y P)(x,\sigma(x)) + \mu\right\|_{L^\infty} = O(\varepsilon).$$

Our main observation is that diamond waves satisfy (5.5) automatically: No smallness assumption is required to prove (5.5). This a consequence of the following general proposition, which is a variation of one of Wu's key results ([45, 46]). Since the result is not restricted to diamond waves, the following result is stated in a little more generality than is needed.

Proposition 5.5. *Let* $\mu > 0$ *and* $c \in \mathbf{R}^2$. *If* (σ, ϕ) *is a* C^2 *solution of* (5.4) *which is doubly periodic in the horizontal variables* x_1 *and* x_2, *then the Taylor sign condition is satisfied:* $(\partial_y P)(x, \sigma(x)) < 0$ *for all* $x \in \mathbf{T}^2$. *As a result it follows from the previous lemma that*

$$\mathfrak{a}(x) > 0,$$

for all $x \in \mathbf{T}^2$.

Remark 5.6. (*i*) In the case of finite depth, it was shown by Lannes ([27]) that the Taylor sign condition is satisfied under an assumption on the second fundamental form of the bottom surface (cf Proposition 4.5 in [27]).

(*ii*) Clearly the previous result is false for $\mu = 0$. Indeed, if $\mu = 0$ then $(\sigma, \phi) = (0, 0)$ solves (5.4).

Proof (from [46, 27]). We have $P = 0$ on the free surface $\{y = \sigma(x)\}$. On the other hand, since $\mu > 0$ and since $\nabla_{x,y}\phi \to 0$ when y tends to $-\infty$, there exists $h > 0$ such that

$$P(x, y) \geq 1 \quad \text{for} \quad y \leq -h.$$

Define

$$\Omega_h = \{(x, y) \in \mathbf{R}^2 \times \mathbf{R} \,:\, -h \leq y \leq \sigma(x)\}.$$

Since P is bi-periodic in x, P reaches its minimum on Ω_h. The key observation is that the equation $\Delta_{x,y}\phi = 0$ implies that

$$\Delta_{x,y} P = -|\nabla_{y,x}\nabla_{y,x}\phi|^2 \leq 0,$$

and hence P is a super-harmonic function. In particular P reaches its minimum on $\partial\Omega_h$ and at such a point we have $\partial_n P < 0$. We conclude the proof by means of the following three ingredients: (i) P reaches its minimum on the free surface since $P|_{y=-h} \geq 1 > 0 = P|_{y=\sigma(x)}$; (ii) $P = 0$ on the free surface so that P reaches its minimum at any point of the free surface, hence $\partial_n P < 0$ on $\{y = \sigma(x)\}$; and (iii) $\partial_n P = \partial_y P$ on the free surface . $\square$

Remark 5.7. According to the Acknowledgments in [46], the idea of expressing $\mathfrak{a}$ as $-(\partial_y P)(x, \sigma(x))$ and using the maximum principle to prove that $-(\partial_y P)(x, \sigma(x)) < 0$ is credited to R. Caflisch and Th. Hou.

After this short détour, we return to the main line of our development. By using the fact that $\mathfrak{a}$ does not vanish, one can form a second order equation from (5.2)–(5.3).

Lemma 5.8. *Set*

$$\mathcal{V}(x,\xi) := -\mathfrak{a}(x)^{-1}(V(x)\cdot\xi)^2 + i\,\mathrm{div}\left(\mathfrak{a}(x)^{-1}(V(x)\cdot\xi)V(x)\right). \tag{5.6}$$

Then,

$$T_{\lambda_\sigma+\mathcal{V}}\, u \in H^{2s-5}(\mathbf{T}^2). \tag{5.7}$$

Remark 5.9. The fact that $\mathfrak{a}$ is positive implies that the symbol $\lambda_\sigma + \mathcal{V}$ may vanish or be arbitrarily small. If $\mathfrak{a}$ were negative, the analysis would have been much easier (cf Section 7.1).

Proof. As already seen we have $\mathfrak{b} \in H^{s-1}(\mathbf{T}^2)$ and $V \in H^{s-1}(\mathbf{T}^2)$. Therefore the product rule in Sobolev space implies that

$$\mathfrak{a} = \mu + V\cdot\nabla\mathfrak{b} \in H^{s-2}(\mathbf{T}^2).$$

Then, by applying Theorem 4.6 with $\rho = s-3$ we obtain that,

$$T_{\mathcal{V}}u - (T_V\cdot\nabla + T_{\mathrm{div}\, V})\, T_{\mathfrak{a}^{-1}}T_V\cdot\nabla u \in H^{s+(s-5)}(\mathbf{T}^2).$$

On the other hand, since $\mathfrak{a}, \mathfrak{a}^{-1} \in H^{s-2}(\mathbf{T}^2)$, Lemma 4.9 implies that

$$T_{\mathfrak{a}^{-1}}T_{\mathfrak{a}} - I \quad \text{is of order } \leq -(s-3),$$

and hence

$$\sigma - (-T_{\mathfrak{a}^{-1}}T_V\cdot\nabla u) \in H^{2s-4}(\mathbf{T}^2). \tag{5.8}$$

The desired result (5.7) is an immediate consequence of (5.2)–(5.3). $\square$

5.3 Notations

The following notations are used continually in this section.

Notation 5.10. i) The set $C(o,e)$ is the set of function $f = f(x_1,x_2)$ which are odd in x_1 and even in x_2. Similarly we define the sets $C(o,o)$, $C(e,o)$ and $C(e,e)$.

ii) The set $\Gamma(o,e)$ is the set of symbols $a = a(x_1,x_2,\xi_1,\xi_2)$ such that

$$\begin{cases} a(-x_1,x_2,-\xi_1,\xi_2) = -a(x_1,x_2,\xi_1,\xi_2), \\ a(x_1,-x_2,\xi_1,-\xi_2) = a(x_1,x_2,\xi_1,\xi_2). \end{cases}$$

Similarly we define the sets $\Gamma(o,o)$, $\Gamma(e,o)$ and $\Gamma(e,e)$.

Remark 5.11. (i) With these notations, by assumption we have $\sigma \in C(e,e)$ and $\psi \in C(o,e)$ so that

$$\mathfrak{b} = \frac{\partial_{x_1}\sigma(1+\partial_{x_1}\psi) + \partial_{x_2}\sigma\partial_{x_2}\psi}{1+|\nabla\sigma|^2} \in C(o,e),$$

and hence $u = \psi - T_{\mathfrak{b}}\sigma \in C(o,e)$. Also, we check that the vector field $V = (V_1, V_2) = c + \nabla\psi - \mathfrak{b}\nabla\sigma$ is such that $V_1 \in C(e,e)$ and $V_2 \in C(o,o)$.

(ii) If $v \in C(o,e)$ and $a \in \Gamma(e,e)$ then $T_a v \in C(o,e)$ (provided that $T_a v$ is well defined). Clearly, the same property is true for the three other classes of symmetric functions.

To simplify the presentation, we will often only check only one half of the symmetry properties which are claimed in the various statements below. We will only check the symmetries with respect to the axis $\{x_1 = 0\}$. To do this, it will be convenient to use the following notation (as in [22]).

Notation 5.12. By notation, given $z = (z_1, z_2) \in \mathbf{R}^2$,

$$z^\star = (-z_1, z_2).$$

5.4 Change of variables

We have just proved that $T_{\lambda_\sigma + \mathcal{V}}\, u \in H^{2s-5}(\mathbf{T}^2)$. We now study the sum of the principal symbols of λ_σ and $\mathcal{V}$. Introduce

$$p(x,\xi) = \sqrt{(1 + |\nabla\sigma(x)|^2)\, |\xi|^2 - (\nabla\sigma(x)\cdot\xi)^2 - \mathfrak{a}(x)^{-1}(V(x)\cdot\xi)^2}.$$

By following the analysis in [22], we shall prove that there exists a change of variables $\mathbf{R}^2 \ni x \mapsto \chi(x) \in \mathbf{R}^2$ such that $p(x, {}^t\chi'(x)\xi)$ has a simple expression.

Since we need to consider change of variables $x \mapsto \chi(x)$ such that $u \circ \chi$ is doubly periodic whenever u is doubly periodic, we introduce the following definition.

Definition 5.13. *Let $\chi \colon \mathbf{R}^2 \to \mathbf{R}^2$ be a continuously differentiable diffeomorphism. For $r > 1$, we say that χ is a $C^r(\mathbf{T}^2)$-diffeomorphism if there exists $\tilde{\chi} \in C^r(\mathbf{T}^2)$ such that*

$$\forall x \in \mathbf{R}^2, \quad \chi(x) = x + \tilde{\chi}(x).$$

(Recall that bi-periodic functions on $\mathbf{R}^2$ are identified with functions on $\mathbf{T}^2$.)

In this paragraph we show

Proposition 5.14. *There exist a $C^{s-4}(\mathbf{T}^2)$-diffeomorphism χ, a constant $\nu \geq 0$, a positive function $\gamma \in C^{s-4}(\mathbf{T}^2)$ and a symbol $\alpha \in \Gamma^0_{s-6}(\mathbf{T}^2)$ homogeneous of degree 0 in ξ such that, for all $(x,\xi) \in \mathbf{T}^2 \times \mathbf{R}^2$,*

$$p(x, {}^t\chi'(x)\xi) = \gamma(x)\big(|\xi| - \nu\xi_1^2\big) + i\alpha(x,\xi)\xi_1,$$

and such that the following properties hold:

i) *$\chi = (\chi^1, \chi^2)$ where $\chi^1 \in C(o,e)$ and $\chi^2 \in C(e,o)$;*

ii) *$\alpha \in \Gamma(o,e)$, $\gamma \in C(e,e)$.*

Proposition 5.14 will be deduced from the following lemma.

Lemma 5.15. *There exists a $C^{s-3}(\mathbf{T}^2)$-diffeomorphism χ_1 of the form*

$$\chi_1(x_1,x_2) = \begin{pmatrix} x_1 \\ d(x_1,x_2) \end{pmatrix},$$

such that d solves the transport equation

$$V(x) \cdot \nabla d(x) = 0,$$

with initial data $d(0,x_2) = x_2$ on $x_1 = 0$, and such that, for all $x \in \mathbf{R}^2$,

$$d(x_1,x_2) = d(-x_1,x_2) = -d(x_1,-x_2), \quad (d \in C(e,o)) \tag{5.9}$$

$$d(x_1,x_2) = d(x_1+2\pi,x_2) = d\,(x_1, x_2+2\pi\ell) - 2\pi\ell. \tag{5.10}$$

Remark 5.16. The result is obvious for the trivial solution $(\sigma,\psi) = (0,0)$ with $d(x) = x_2$. It can be easily inferred from the analysis in Appendix C in [22] that this result is also satisfied in a neighborhood of $(0,0)$. The new point here is that we prove the result under the only assumption that (σ,ϕ) satisfies condition (2.2) in Definition 2.2.

Proof. Assumption (2.2) implies that $V_1(x) \neq 0$ for all $x \in \mathbf{T}^2$. We first write that, if d satisfies $V \cdot \nabla d = 0$ with initial data $d(0,x_2) = x_2$ on $x_1 = 0$, then $w = \partial_{x_2} d$ solves the Cauchy problem

$$\partial_{x_1} w + \frac{V_2}{V_1}\partial_{x_2} w + w\partial_{x_2}\left(\frac{V_2}{V_1}\right) = 0, \qquad w(0,x_2) = 1. \tag{5.11}$$

To study this Cauchy problem, we work in the Sobolev spaces of $2\pi\ell$-periodic functions $H^s(T)$ where T is the circle $T := \mathbf{R}/(2\pi\ell\mathbf{Z})$. Since

$$V_2/V_1, \partial_{x_2}(V_2/V_1) \in H^{s-2}(\mathbf{T}^2) \subset L^\infty(\mathbf{R}; H^{s-3}(T)),$$

and since $s > 4$, standard results for hyperbolic equations imply that (5.11) has a unique solution $w \in C^0(\mathbf{R}; H^{s-3}(T))$. We define d by

$$d(x_1,x_2) := \int_0^{x_2} w(x_1,t)\,dt. \tag{5.12}$$

We then obtain a solution of $V \cdot \nabla d = 0$, and we easily checked that

$$d(x) - x_2 \in \bigcap_{0 \le j < s-2} C^j(\mathbf{R}; H^{s-2-j}(T)).$$

The Sobolev embedding thus implies that $d(x) - x_2 \in C^{s-3}(\mathbf{R}^2)$.

We next prove that d satisfies (5.9)–(5.10). Firstly, by uniqueness for the Cauchy problem (5.11), using that V_1, V_2 are $2\pi\ell$-periodic in x_2 and using the symmetry properties of V_1, V_2 (cf Remark 5.11) we easily obtain

$$w(x_1, x_2) = w(-x_1, x_2) = w(x_1, -x_2) = w\left(x_1, x_2 + 2\pi\ell\right).$$

To prove that w is periodic in x_1, following [22], we use in a essential way the fact that w is even in x_1 to write

$$w(-\pi, x_2) = w(+\pi, x_2),$$

which yields, by uniqueness for the Cauchy problem,

$$w(x_1 - \pi, x_2) = w(x_1 + \pi, x_2).$$

This proves that w is 2π-periodic in x_1. Next, directly from the definition (5.12), we obtain that d is 2π-periodic in x_1 and that d satisfies (5.9). Moreover, this yields

$$d\left(x_1, x_2 + 2\pi\ell\right) - d(x_1, x_2) = \int_0^{2\pi\ell} w(x_1, x_2)\, dx_2.$$

Differentiating the right-hand side with respect to x_1, and using the identity $\partial_{x_1} w = -\partial_{x_2}(V_2 w/V_1)$, we obtain

$$\int_0^{2\pi\ell} w(x_1, x_2)\, dx_2 = \int_0^{2\pi\ell} w(0, x_2)\, dx_2 = 2\pi\ell,$$

which completes the proof of (5.10).

We next prove that

$$\forall x \in \mathbf{T}^2, \quad w(x) = \partial_{x_2} d(x) \neq 0. \tag{5.13}$$

Suppose for contradiction that there exists $x \in [0, 2\pi) \times [0, 2\pi\ell)$ such that $w(x) = 0$. Set

$$\alpha = \inf\{x_1 \in [0, 2\pi) \,:\, \exists x_2 \in [0, 2\pi\ell] \text{ s.t. } w(x_1, x_2) = 0\}.$$

By continuity, there exists y such that $w(\alpha, y) = 0$. Since $w(0, x_2) = 1$, we have $\alpha > 0$. For $0 \leq x_1 < \alpha$, we compute that $1/w$ satisfies

$$\left(\partial_{x_1} + \frac{V_2}{V_1}\partial_{x_2} - \partial_{x_2}\left(\frac{V_2}{V_1}\right)\right)\frac{1}{w} = 0, \qquad \frac{1}{w}(0, x_2) = 1.$$

Let $0 < \delta < 1$. By Sobolev embedding, there exists a constant K such that

$$\sup_{(x_1, x_2) \in [0, \delta\alpha] \times [0, 2\pi\ell]} \left|\frac{1}{w}(x_1, x_2)\right| \leq K \sup_{x_1 \in [0, \delta\alpha]} \left\|\frac{1}{w}(x_1, \cdot)\right\|_{H^1(T)}.$$

Therefore, classical energy estimates imply that

$$\sup_{(x_1,x_2)\in[0,\delta\alpha]\times[0,2\pi\ell]}\left|\frac{1}{w}(x)\right|\le(K+KC)e^{4C\alpha}$$

with

$$C:=\sup_{x_1\in[0,\delta\alpha]}\left\|\frac{V_2}{V_1}(x_1,\cdot)\right\|_{C^2(T)}.$$

Therefore, if $0\le x_1<\alpha$, then

$$w(x)>(K+KC)^{-1}e^{-4C\alpha}.$$

This gets us to $w(\alpha,\cdot)>0$, whence the contradiction which proves (5.13). Consequently, $\det\chi'(x)\neq 0$ for all $x\in\mathbf{R}^2$. The above argument also establishes that there exists a constant $c\ge 1$ such that, for all $x\in\mathbf{R}^2$,

$$\frac{x_2}{c}\le d(x)\le cx_2.$$

This implies that χ_1 is a diffeomorphism of $\mathbf{R}^2$, which completes the proof.

□

The end of the proof of Proposition 5.14 follows from Section 3 in [22].

Firstly, directly from the identity $V\cdot\nabla d=0$, we obtain

$$V(x)\cdot({}^t\chi_1'(x)\xi)=V_1(x)\xi_1,$$

and hence

$$p(x,{}^t\chi_1'(x)\xi)=\lambda_\sigma^1(x,{}^t\chi_1'(x)\xi)-\mathfrak{a}(x)^{-1}(V_1(x)\xi_1)^2.$$

Our next task is to rewrite $\lambda_\sigma^1(x,{}^t\chi_1'(x)\xi)$ in an appropriate form.

Lemma 5.17. *There holds*

$$\lambda_\sigma^1(x,{}^t\chi_1'(x)\xi)=\lambda_\sigma^1\left(x,{}^t\chi_1'(x)\begin{pmatrix}0\\1\end{pmatrix}\right)|\xi|+ir(x,\xi)\xi_1,\tag{5.14}$$

where $r\in\Gamma^0_{s-4}(\mathbf{T}^2)$ is homogeneous of degree 0 in ξ and such that

$$r\in\Gamma(o,e).$$

Proof. This follows from the fact that $\lambda_\sigma^1(x,{}^t\chi_1'(x)\xi)$ is the square root of an homogeneous polynomial function of degree 2 in ξ. Indeed, write $\lambda_\sigma^1(x,{}^t\chi_1'(x)\xi)^2$ under the form

$$\lambda_\sigma^1(x,{}^t\chi_1'(x)\xi)^2=P_1(x)\xi_1^2+P_{12}(x)\xi_1\xi_2+P_2(x)\xi_2^2.\tag{5.15}$$

Then

$$\lambda_\sigma^1(x, {}^t\chi_1'(x)\xi)^2 - P_2(x)\left|\xi\right|^2 = \left(P_1(x) - P_2(x)\right)\xi_1^2 + P_{12}(x)\xi_1\xi_2.$$

Directly from (5.15) applied with $\xi = e_2 := \left(\begin{smallmatrix}0\\1\end{smallmatrix}\right)$, we get

$$P_2(x) = \lambda_\sigma^1\left(x, {}^t\chi_1'(x)e_2\right)^2. \tag{5.16}$$

Since $\lambda_\sigma \geq 0$, using the elementary identity $\sqrt{a} - \sqrt{b} = (a-b)/(\sqrt{a} + \sqrt{b})$, we obtain the desired result (5.14) with

$$r(x,\xi) = -i\frac{\left(P_1(x) - P_2(x)\right)\xi_1 + P_{12}(x)\xi_2}{\lambda_\sigma^1(x, {}^t\chi_1'(x)\xi) + \sqrt{P_2(x)}\left|\xi\right|}.$$

Since $d \in C^{s-3}(\mathbf{R}^2)$, we verify that r belongs to $\Gamma^0_{s-4}(\mathbf{T}^2)$. It remains to show that $r(x,\xi) \in \Gamma(o,e)$. To fix idea we study the symmetry with respect to the change of variables $(x,\xi) \mapsto (x^\star, \xi^\star)$ (see Notation 5.12). We want to prove that $r(x^\star, \xi^\star) = -r(x,\xi)$. To see this, r is better written as

$$r(x,\xi) = -i\frac{1}{\xi_1}\frac{(\lambda_\sigma^1(x, {}^t\chi_1'(x)\xi))^2 - P_2(x)\left|\xi\right|^2}{\lambda_\sigma^1(x, {}^t\chi_1'(x)\xi) + \sqrt{P_2(x)}\left|\xi\right|}.$$

Note that (5.9) implies that ${}^t\chi_1'(x^\star)\xi^\star = \left[{}^t\chi_1'(x)\xi\right]^\star$ which in turn implies that $\lambda_\sigma^1(x^\star, {}^t\chi_1'(x^\star)\xi^\star) = \lambda_\sigma^1(x, {}^t\chi_1'(x)\xi)$. Moreover, directly from the definition of P_2 we see that $P_2(x^\star) = P_2(x)$. This yields the desired result $r(x^\star, \xi^\star) = -r(x,\xi)$. □

Introduce next the symbol p_1 given by

$$p_1(\chi_1(x), \xi) := p(x, {}^t\chi_1'(x)\xi).$$

Lemma 5.18. *There exists a constant $\nu \geq 0$, a $C^{s-4}(\mathbf{T}^2)$-diffeomorphism χ_2, a positive function $M \in C^{s-4}(\mathbf{T}^2)$ and a symbol $\widetilde{\alpha} \in \Gamma^0_{s-6}(\mathbf{T}^2)$ homogeneous of degree 0 in ξ such that, for all $(x,\xi) \in \mathbf{T}^2 \times \mathbf{R}^2$,*

$$p_1(x, {}^t\chi_2'(x)\xi) = M(x)\left(\left|\xi\right| - \nu\xi_1^2\right) + i\widetilde{\alpha}(x,\xi)\xi_1,$$

and such that the following properties hold: $M \in C(e,e)$ and $\widetilde{\alpha} \in \Gamma(o,e)$, and χ_2 is of the form

$$\chi_2(x_1, x_2) = \begin{pmatrix} x_1 + \widetilde{d}(x_1, x_2) \\ x_2 + \widetilde{e}(x_2) \end{pmatrix}, \tag{5.17}$$

where $\widetilde{d} \in C^{s-4}(\mathbf{T}^2)$ is odd in x_1 and even in x_2, and $\widetilde{e} \in C^{s-3}(\mathbf{R}/2\pi\ell\mathbf{Z})$ is odd in x_2.

Proof. If χ_2 is of the form (5.17), then

$$
{}^t\chi_2'(x)\begin{pmatrix}\xi_1\\ \xi_2\end{pmatrix} = \begin{pmatrix}(1+\partial_{x_1}\widetilde{d}(x))\xi_1\\ \partial_{x_2}\widetilde{d}(x)\xi_1 + (1+\partial_{x_2}\widetilde{e}(x_2))\xi_2\end{pmatrix}.
$$

By transforming the symbols as in the proof of Lemma 5.17, we find that it is sufficient to find $\nu \geq 0$, $\widetilde{d} = \widetilde{d}(x_1, x_2)$ and $\widetilde{e} = \widetilde{e}(x_2)$ such that

$$
(1+\partial_{x_1}\widetilde{d}(x_1,x_2))^2 = \nu\Gamma(x)(1+\partial_{x_2}\widetilde{e}(x_2)), \quad \text{where } \Gamma(x) := \frac{P_2\mathfrak{a}}{V_1^2}(\chi_1^{-1}(x)).
$$

Therefore, we set

$$
\widetilde{d}(x_1,x_2) = \int_0^{x_1} \sqrt{\nu\Gamma(t,x_2)(1+\partial_{x_2}\widetilde{e}(x_2))}\,dt - x_1.
$$

Then, $\widetilde{d}$ is 2π-periodic in x_1 if and only if,

$$
\forall x_2 \in [0, 2\pi\ell], \qquad \sqrt{\nu(1+\partial_{x_2}\widetilde{e}(x_2))}\int_0^{2\pi} \sqrt{\Gamma(x_1,x_2)}\,dx_1 - 2\pi = 0.
$$

This yields an equation for $\widetilde{e} = \widetilde{e}(x_2)$ which has a $(2\pi\ell)$-periodic solution if and only if ν is given by

$$
\nu := \frac{2\pi}{\ell}\int_0^{2\pi\ell}\left(\int_0^{2\pi}\sqrt{\Gamma(x_1,x_2)}\,dx_1\right)^{-2} dx_2.
$$

Now, notice that there exists a positive constant C such that $P_2 \geq C$ (by definition of P_2, cf (5.16)), $\mathfrak{a} \geq C$ (by Proposition 5.5), $V_1^2 \geq C$ (by the assumption (2.2)). Hence, with ν, $\widetilde{d}$ and $\widetilde{e}$ as previously determined, we easily check that χ_2 is a $C^{s-4}(\mathbf{T}^2)$-diffeomorphism. □

To complete the proof of Proposition 5.14, set

$$
\chi(x) = \chi_2(\chi_1(x)),
$$

to obtain

$$
\begin{aligned}
p(x, {}^t\chi'(x)\xi) &= p(x, {}^t\chi_1'(x){}^t\chi_2'(\chi_1(x))\xi)\\
&= p_1(\chi_1(x), {}^t\chi_2'(\chi_1(x))\xi)\\
&= M(\chi_1(x))\left(|\xi| - \nu\xi_1^2\right) + i\widetilde{\alpha}(\chi_1(x),\xi)\xi_1,
\end{aligned}
$$

so that we obtain the desired result with

$$
\gamma(x) = M(\chi_1(x)), \quad \alpha(x,\xi) = \widetilde{\alpha}(\chi_1(x),\xi).
$$

5.5 Paracomposition

To compute the effect of the change of variables $x \mapsto \chi(x)$, we shall use Alinhac's paracomposition operators. We refer to [1, 41] for general theory about Alinhac's paracomposition operators. We here briefly state the basic definitions and results for periodic functions. Roughly speaking, these results assert that, given $r > 1$, one can associate to a $C^r(\mathbf{T}^2)$-diffeomorphism χ an operator χ^* of order ≤ 0 such that, on the one hand,

$$\forall \alpha \in \mathbf{R}, \quad u \in H^\alpha(\mathbf{T}^2) \Leftrightarrow \chi^* u \in H^\alpha(\mathbf{T}^2),$$

and on the other hand, there is a symbolic calculus to compute the commutator of χ^* to a paradifferential operator.

Let $\phi\colon \mathbf{R} \to \mathbf{R}$ be a smooth even function with $\phi(t) = 1$ for $|t| \leq 1.1$ and $\phi(t) = 0$ for $|t| \geq 1.9$. For $k \in \mathbf{Z}$, we introduce the symbol

$$\phi_k(\xi) = \phi\left(2^{-k}(1 + |\xi|^2)^{1/2}\right),$$

and then the operator

$$\widehat{\Delta_k f}(\xi) := (\phi_k(\xi) - \phi_{k-1}(\xi))\, \widehat{f}(\xi).$$

For all temperate distribution $f \in \mathcal{S}'(\mathbf{R}^d)$, the spectrum of $\Delta_k f$ satisfies $\operatorname{spec} \Delta_k f \subset \{\xi \,:\, 2^{k-1} < \langle \xi \rangle < 2^{k+1}\}$. Hence $\Delta_k f = 0$ when $k < 0$. Thus, one has the Littlewood–Paley decomposition:

$$f = \sum_{k \geq 0} \Delta_k f.$$

Definition 5.19. *Let χ be a $C^r(\mathbf{T}^2)$ diffeomorphism with $r > 1$. By definition*

$$\chi^* f = \sum_{j \in \mathbf{N}} \sum_{|k-j| \leq N} \Delta_k \left((\Delta_j f) \circ \chi \right),$$

where N is large enough (depending on $\|\tilde{\chi}\|_{C^1}$ only, where $\tilde{\chi}(x) = \chi(x) - x$).

Two of the principal facts about paracomposition operators are the following theorems, whose proofs follow from [1] by adapting the analysis to the case of $C^r(\mathbf{T}^2)$-diffeomorphisms. The first basic result is that χ^* is an operator of order ≤ 0 which can be inverted in the following sense.

Theorem 5.20. *Let χ be a C^r-diffeomorphism with $r > 1$. For all $\alpha \geq 0$, $f \in H^\alpha(\mathbf{T}^2)$ if and only if $\chi^* f \in H^\alpha(\mathbf{T}^2)$. Moreover, $\chi^*(\chi^{-1})^* - I$ is of order $\leq -(r-1)$.*

This theorem reduces the study of the regularity of u to the study of the regularity of $\chi^* u$. To study the regularity of $\chi^* u$ we need to compute the equation satisfied by $\chi^* u$. To do this, we shall use a symbolic calculus theorem which allows to compute the equation satisfied by $\chi^* u$ in terms of the equation satisfied by u (in analogy with the paradifferential calculus). For what follows, it is convenient to work with $(\chi^{-1})^*$.

Theorem 5.21. *Let $m \in \mathbf{R}$, $r > 1$, $\rho > 0$ and set $\sigma := \inf\{\rho, r-1\}$. Consider a $C^r(\mathbf{T}^2)$-diffeomorphism χ and a symbol $a \in \Sigma^m_\rho(\mathbf{T}^2)$, then there exists $a^* \in \Sigma^m_\sigma(\mathbf{T}^2)$ such that*

$$(\chi^{-1})^* T_a - T_{a^*}(\chi^{-1})^* \quad \textit{is order } \leq m - \sigma.$$

Moreover, one can give an explicit formula for a^*: If one decomposes a as a sum of homogeneous symbols, then

$$a^*(\chi(x), \eta) = \sum \frac{1}{i^\alpha \alpha!} \partial_\xi^\alpha a_{m-k}(x, {}^t\chi'(x)\eta) \partial_y^\alpha (e^{i\Psi_x(y)\cdot\eta})|_{y=x}, \tag{5.18}$$

where the sum is taken over all $\alpha \in \mathbf{N}^2$ such that the summand is well defined, $\chi'(x)$ is the differential of χ, t denotes transpose and

$$\Psi_x(y) = \chi(y) - \chi(x) - \chi'(x)(y-x). \tag{5.19}$$

5.6 The first reduction

We here apply the previous results to perform a first reduction to a case where the “principal” part of the equation has constant coefficient.

Proposition 5.22. *Let χ be as given by Proposition 5.14. Then $(\chi^{-1})^* u$ satisfies an equation of the form*

$$\Big(|D_x| + \nu \partial_{x_1}^2 + T_A \partial_{x_1} + T_B\Big) (\chi^{-1})^* u = f \in H^{s+2}(\mathbf{T}^2), \tag{5.20}$$

where $A \in \Gamma^0_{s-6}(\mathbf{T}^2)$ and $B \in \Sigma^0_{s-6}(\mathbf{T}^2)$ are such that:

- i) *A is homogeneous of degree 0 in ξ; $B = B_0 + B_{-1}$ where B_ℓ is homogeneous of degree ℓ in ξ;*
- ii) *$A \in \Gamma(o,e)$ and $B_\ell \in \Gamma(e,e)$ for $\ell = 0, 1$.*

Remark 5.23. (i) For what follows it is enough to have remainders in $H^{s+2}(\mathbf{T}^2)$. From now on, to simplify the presentation we do not try to give results with remainders having a regularity higher than what is needed.

(ii) $A \in \Gamma(o,e)$ and $B_\ell \in \Gamma(e,e)$ is equivalent to the fact that the symbol of $|D_x| + \nu\partial_{x_1}^2 + T_A\partial_{x_1} + T_B$ is invariant by the symmetries

$$(x_1, x_2, \xi_1, \xi_2) \mapsto (-x_1, x_2, -\xi_1, \xi_2),$$
$$(x_1, x_2, \xi_1, \xi_2) \mapsto (x_1, -x_2, \xi_1, -\xi_2).$$

Proof. We begin by applying the results in §5.5 to compute the equation satisfies by $(\chi^{-1})^* u$. Recall that, by notation, $\mathcal{V}$ is as given by (5.6) and

$$p(x,\xi) = \sqrt{(1+|\nabla\sigma|^2)\,|\xi|^2 - (\nabla\sigma\cdot\xi)^2} - \mathfrak{a}(x)^{-1}(V(x)\cdot\xi)^2.$$

We define λ_σ^* by (5.18) applied with $m=1$ and $\rho = s-1$. Similarly, we define $\mathcal{V}^*$ and p^* by (5.18) applied with $m=2$ and $\rho = s-4$. To prove Proposition 5.22, the key step is to compare the principal symbol of p^* with $\lambda_\sigma^* + \mathcal{V}^*$.

Lemma 5.24. *There exist $a \in \Gamma^0_{s-6}(\mathbf{T}^2)$ and $b = b_0 + b_{-1} \in \Sigma^0_{s-6}(\mathbf{T}^2)$ and a remainder $r \in \Sigma^{-2}_{s-8}(\mathbf{T}^2)$ such that*

$$\lambda_\sigma^*(\chi(x),\xi) + \mathcal{V}^*(\chi(x),\xi) = p(x, {}^t\chi'(x)\xi) + ia(x,\xi)\xi_1 + b(x,\xi) + r(x,\xi),$$

and such that $a \in \Gamma(o,e)$, $b \in \Gamma(e,e)$.

Proof. The proof is elementary. We first study $\lambda_\sigma^*(\chi(x),\xi)$. Since λ_σ is a symbol of order 1, to obtain a remainder r which is of order -2, we need to compute the first three terms in the symbolic expansion of λ_σ^*. To do this, note that there are some cancelations which follow directly from the definition (5.19):

$$\begin{aligned}
|\alpha| = 1 \quad &\Rightarrow \partial_y^\alpha (e^{i\Psi_x(y)\cdot\xi})|_{y=x} = 0,\\
2 \le |\alpha| \le 3 \quad &\Rightarrow \partial_y^\alpha (e^{i\Psi_x(y)\cdot\xi})|_{y=x} = i\partial_x^\alpha(\chi(x)\cdot\xi),\\
|\alpha| = 4 \quad &\Rightarrow \partial_y^\alpha (e^{i\Psi_x(y)\cdot\xi})|_{y=x} = i\partial_x^\alpha(\chi(x)\cdot\xi) - \sum \partial_x^\beta(\chi(x)\cdot\xi)\partial_x^\gamma(\chi(x)\cdot\xi),
\end{aligned}$$

where in the last line the sum is taken over all decompositions $\beta+\gamma=\alpha$ such that $|\beta| = 2 = |\gamma|$. Therefore, it follows from (5.18) that

$$\lambda_\sigma^*(\chi(x),\xi) = \lambda_\sigma^1(x, {}^t\chi'(x)\xi) + b_0(x,\xi) + b_{-1}(x,\xi) + r(x,\xi), \tag{5.21}$$

where $r \in \Sigma^{-2}_{s-8}(\mathbf{T}^2)$ and

$$\begin{aligned}
b_0(x,\xi) &:= \lambda_\sigma^0(x, {}^t\chi'(x)\xi) - i\sum_{|\alpha|=2} \frac{1}{\alpha!}(\partial_\xi^\alpha\lambda_\sigma^1)(x, {}^t\chi'(x)\xi)\partial_x^\alpha\chi(x)\cdot\xi,\\
b_{-1}(x,\xi) &:= \lambda_\sigma^{-1}(x, {}^t\chi'(x)\xi) + \sum_{\ell=0}^{1}\sum_{|\alpha|=2+\ell} \frac{1}{i^\alpha\alpha!}(\partial_\xi^\alpha\lambda_\sigma^\ell)(x, {}^t\chi'(x)\xi)\partial_x^\alpha\chi(x)\cdot\xi\\
&\qquad - \sum_{|\beta|=2=|\gamma|}(\partial_\xi^{\beta+\gamma}\lambda_\sigma^1)(x, {}^t\chi'(x)\xi)(\partial_x^\beta\chi(x)\cdot\xi)(\partial_x^\gamma\chi(x)\cdot\xi).
\end{aligned}$$

Recall that $\chi = (\chi^1,\chi^2)$ where χ^1 is odd in x_1 and even in x_2, and χ^2 is even in x_1 and odd in x_2. Therefore, to prove the desired symmetry properties, it is sufficient to prove that $\lambda_\sigma^1, \lambda_\sigma^0, \lambda_\sigma^{-1}$ are invariant by the two changes of variables

$$\begin{aligned}(x_1,x_2,\xi_1,\xi_2)&\mapsto(-x_1,x_2,-\xi_1,\xi_2),\\(x_1,x_2,\xi_1,\xi_2)&\mapsto(x_1,-x_2,\xi_1,-\xi_2).\end{aligned}$$

We consider the first case only and use the notation

$$f^\star(x_1,x_2)=f(-x_1,x_2).$$

Observe that, since $\sigma^\star=\sigma$, it follows directly from the definition of the Dirichlet to Neumann operator (see (2.11)) that

$$G(\sigma)f^\star=\big[G(\sigma)f\big]^\star.$$

On the symbol level, this immediately gives the desired result:

$$\lambda_\sigma(x^\star,\xi^\star)=\lambda_\sigma(x,\xi).$$

Alternatively, one may use the explicit definition of the symbols A_m given in the proof of Lemma 4.13.

Since, by notation,

$$\mathcal{V}(x,\xi):=-\mathfrak{a}(x)^{-1}(V(x)\cdot\xi)^2+i\operatorname{div}\Big(\mathfrak{a}(x)^{-1}(V(x)\cdot\xi)V(x)\Big),$$

the same reasoning implies that

$$\begin{aligned}\mathcal{V}^*(\chi(x),\xi)=&-\mathfrak{a}^{-1}(V(x)\cdot{}^t\chi'(x)\xi)^2+i\mathfrak{a}(x)^{-1}(V(x)\cdot{}^t\chi'(x)\xi)\operatorname{div}V(x)\\&+i\mathfrak{a}(x)^{-1}\left(V(x)\cdot\nabla V(x)\right)\cdot{}^t\chi'(x)\xi\\&+i\mathfrak{a}(x)^{-1}\sum_{1\le k,\ell\le 2}V_k(x)V_\ell(x)\partial_{x_k}\partial_{x_\ell}(\chi(x)\cdot\xi).\end{aligned}$$

Gathering the last two terms in the right-hand side we thus obtain

$$\begin{aligned}\mathcal{V}^*(\chi(x),\xi)=&-\mathfrak{a}^{-1}(V(x)\cdot{}^t\chi'(x)\xi)^2+i\mathfrak{a}(x)^{-1}(V(x)\cdot{}^t\chi'(x)\xi)\operatorname{div}V(x)\\&+i\mathfrak{a}(x)^{-1}V(x)\cdot\nabla\Big(V(x)\cdot{}^t\chi'(x)\xi\Big)\end{aligned}$$

and hence, by construction of χ, it follows that

$$\mathcal{V}^*(\chi(x),\xi)=-\mathfrak{a}(x)^{-1}(V(x)\cdot{}^t\chi'(x)\xi)^2+ia(x,\xi)\xi_1,$$

where $a\in\Gamma^0_{s-5}(\mathbf{T}^2)$ is such that $a\in\Gamma(o,e)$. This completes the proof of Lemma 5.24. □

We now are now in position to prove Proposition 5.22. By using Theorem 5.21, it follows from Lemma 5.24 and Proposition 5.14 that

$$\Big(T_\gamma(|D_x|+\nu\partial_{x_1}^2)+T_{\alpha+a}\partial_{x_1}+T_b\Big)(\chi^{-1})^*u\in H^{s+2}(\mathbf{T}^2).$$

We thus obtain (5.20) with $A=(\alpha+a)/\gamma$ and $B=b/\gamma$. □

5.7 Elliptic regularity far from the characteristic variety

As usual, the analysis makes use of the division of the phase space into a region in which the inverse of the symbol remains bounded by a fixed constant and a region where the symbol is small and may vanish. Here we consider the easy part and prove the following elliptic regularity result.

Proposition 5.25. *Let χ be the diffeomorphism determined in Proposition 5.14. Consider $\Theta = \Theta(\xi)$ homogenous of degree 0 and such that there exists a constant K such that*

$$|\xi_2| \geq K |\xi_1| \Rightarrow \Theta(\xi_1, \xi_2) = 0.$$

Then,

$$\Theta(D_x)((\chi^{-1})^* u) \in H^{s+2}(\mathbf{T}^2).$$

Remark 5.26. Note that, on the characteristic variety, we have $|\xi_2| \sim \nu\xi_1^2$. On the other hand, on the spectrum of $\Theta(D_x)((\chi^{-1})^* u)$, we have $|\xi_2| \leq K|\xi_1|$. Therefore, the previous result establishes elliptic regularity very far from the characteristic variety.

Proof. Recall that $(\chi^{-1})^* u$ satisfies (5.20). Set

$$\wp(x,\xi) := |\xi| - \nu\xi_1^2 + iA(x,\xi)\xi_1 + B(x,\xi).$$

We have

$$T_\wp((\chi^{-1})^* u) \in H^{s+2}(\mathbf{T}^2). \tag{5.22}$$

Note that $|\wp(x,\xi)| \geq c|\xi|^2$ for some constant $c > 0$ for all (x,ξ) such that

$$|\xi_2| \leq K|\xi_1| \quad \text{and} \quad |\xi| \geq M,$$

for some large enough constant M depending on $\sup_{x,\xi} |A(x,\xi)| + |B(x,\xi)|$. Introduce a C^∞ function $\tilde{\Theta}$ such that

$$\begin{aligned} &\tilde{\Theta}(\xi) = 0 \quad \text{for} \quad |\xi| \leq M, \\ &\tilde{\Theta}(\xi) = \Theta(\xi) \quad \text{for} \ |\xi| \geq 2M. \end{aligned}$$

Since Θ and $\tilde{\Theta}$ differ only on a bounded neighborhood of the origin, we have

$$\Theta(D_x)((\chi^{-1})^* u) - \tilde{\Theta}(D_x)((\chi^{-1})^* u) \in C^\infty(\mathbf{T}^2).$$

Note that, since Θ is positively homogeneous of degree 0, $\tilde{\Theta}$ belongs to our symbol class ($\tilde{\Theta} \in \Gamma^0_\rho(\mathbf{T}^2)$ for all $\rho \geq 0$). Set

$$q = \frac{\tilde{\Theta}}{\wp} - \frac{1}{i}\partial_\xi\left(\frac{\tilde{\Theta}}{\wp}\right)\frac{\partial_x \wp}{\wp} \in \Gamma^{-2}_{s-8}(\mathbf{T}^2).$$

According to Theorem 4.6 applied with $(m, m', \rho) = (2, -2, 2)$, then,

$$T_q T_\wp((\chi^{-1})^* u) - \tilde{\Theta}(D_x)((\chi^{-1})^* u) \in H^{s+2}(\mathbf{T}^2).$$

On the other hand, since T_q is of order ≤ 0, it follows from (5.22) that

$$T_q T_\wp((\chi^{-1})^* u) \in H^{s+2}(\mathbf{T}^2).$$

Which completes the proof. $\square$

5.8 The second reduction and the end of the proof of Theorem 2.5

We first set a few notations. Introduce a C^∞ function η such that $0 \leq \eta \leq 1$,

$$\eta(t) = 0 \quad \text{for } t \in [-1/2, 1/2], \qquad \eta(t) = 1 \quad \text{for } |t| \geq 1. \tag{5.23}$$

Given $k \in \mathbf{N}$, $\partial_{x_1}^{-k}$ denotes the Fourier multiplier (defined on $\mathcal{S}'(\mathbf{R}^d)$) with symbol $\eta(\xi_1)(i\xi_1)^{-k}$. Note that, if f is 2π-periodic in x_1, then

$$\partial_{x_1}^0 f = f - \frac{1}{2\pi} \int_0^{2\pi} f(x_1, x_2)\, dx_2,$$

and

$$(\partial_{x_1}^{-1} f)(x_1, x_2) = \int_0^{x_1} \left(f(s, x_2) - \frac{1}{2\pi} \int_0^{2\pi} f(x_1, x_2)\, dx_1 \right) ds.$$

In particular, $\partial_{x_1} \partial_{x_1}^{-1} f = \partial_{x_1}^0 f = f$ if and only if f has zero mean value in x_1. We also have

$$\partial_{x_1}^{-k-1} f = \partial_{x_1}^{-k} \partial_{x_1}^{-1} f.$$

It will be convenient to divide the frequency space into three pieces so that, in the two main parts, ξ_2 is either positive or negative. To do this, we need to use Fourier multipliers whose symbols belong to our symbol class, which is necessary to apply symbolic calculus in the forthcoming computations. Here is one way to define such Fourier multipliers: consider a C^∞ function J satisfying $0 \leq J \leq 1$ and such that,

$$J(s) = 0 \quad \text{for } s \leq 0.8, \qquad J(s) = 1 \quad \text{for } s \geq 0.9, \tag{5.24}$$

We define three C^∞ functions $\jmath_0, \jmath_-$ and $\jmath_+$ by

$$\jmath_0 = 1 - \jmath_- - \jmath_+, \quad \jmath_-(\xi) = J\left(\frac{|\xi| - \xi_2}{2\,|\xi|} \right), \quad \jmath_+(\xi) = J\left(\frac{|\xi| + \xi_2}{2\,|\xi|} \right),$$

and then the Fourier multipliers

$$\widehat{\jmath_\varepsilon(D_x) f}(\xi) = \jmath_\varepsilon(\xi) \widehat{f}(\xi) \qquad (\varepsilon \in \{0, -, +\}).$$

Note that there are constants $0 < c_1 < c_2$ such that

$$\xi_2 \le c_1 |\xi_1| \Rightarrow j_+(\xi) = 0, \qquad \xi_2 \ge c_2 |\xi_1| \Rightarrow j_+(\xi) = 1, \tag{5.25}$$

$$\xi_2 \ge -c_1 |\xi_1| \Rightarrow j_-(\xi) = 0, \qquad \xi_2 \le -c_2 |\xi_1| \Rightarrow j_-(\xi) = 1. \tag{5.26}$$

Also, note that $\jmath_\pm$ is positively homogeneous of degree 0 and hence satisfies

$$\left| \partial_\xi^\alpha \jmath_\pm(\xi) \right| \le C_\alpha |\xi|^{-|\alpha|}.$$

In view of (5.25) and (5.26), Proposition 5.25 implies that

$$\jmath_0(D_x)((\chi^{-1})^* u) \in H^{s+2}(\mathbf{T}^2). \tag{5.27}$$

As a result, it remains only to concentrate on the two other terms:

$$\jmath_\pm(D_x)\left((\chi^{-1})^* u \right).$$

Here is one other obvious observation that enable us to reduce the analysis to the study of only one of these two terms: Since $(\chi^{-1})^* u$ is even in x_2, we have

$$\widehat{(\chi^{-1})^* u}(\xi_1, \xi_2) = \widehat{(\chi^{-1})^* u}(\xi_1, -\xi_2),$$

Therefore,

$$\jmath_-(D_x)\left((\chi^{-1})^* u \right) \text{ and } \jmath_+(D_x)\left((\chi^{-1})^* u \right) \text{ have the same regularity.} \tag{5.28}$$

Consequently, it suffices to study one of these two terms. We chose to work with

$$U := \jmath_+(D_x)\left((\chi^{-1})^* u \right).$$

We shall prove that one can transform further the problem to a linear equation with *constant* coefficients, using the method of Iooss and Plotnikov [22]. The key to proving Theorem 5.1 is the following.

Proposition 5.27. *There exist two constants $\kappa, \kappa' \in \mathbf{R}$ and an operator*

$$Z_c = \sum_{0 \le j \le 4} T_{c_j} \partial_{x_1}^{-j},$$

where $c_0, \dots, c_4 \in C^1(\mathbf{T}^2)^5$ and $|c_0| > 0$, such that

$$\left(-i\partial_{x_2} + \nu \partial_{x_1}^2 + \kappa + \kappa' \partial_{x_1}^{-2} \right) Z_c U \in H^{s+2}(\mathbf{T}^2). \tag{5.29}$$

Proof. Proposition 5.27 is proved in §5.9 and §5.10. □

We here explain how to conclude the proof of Theorem 5.1.

Proof of Theorem 5.1 given Proposition 5.27. Since the symbol of the operator $-i\partial_{x_2} + \nu\partial_{x_1}^2 + \kappa + \kappa'\partial_{x_1}^{-2}$ is $\xi_2 - \nu\xi_1^2 + \kappa - \kappa'\xi_1^{-2}$, we set

$$\nu(\omega) = \ell\nu, \quad \kappa_0(\omega) = -\ell\kappa, \quad \kappa_1(\omega) = \ell\kappa'.$$

Assume that there exist $\delta \in [0,1[$ and $N \in \mathbf{N}^*$ such that,

$$\left| k_2 - \nu(\omega)k_1^2 - \kappa_0(\omega) - \frac{\kappa_1(\omega)}{k_1^2} \right| \geq \frac{1}{k_1^{2+\delta}},$$

for all $k \in \mathbf{N}^2$ with k_1 sufficiently large.

Directly from the definitions of the coefficients, this assumption implies that

$$\left| \xi_2 - \nu\xi_1^2 + \kappa - \frac{\kappa'}{\xi_1^2} \right| \geq \frac{1}{\ell\xi_1^{2+\delta}},$$

for all $\xi = (\xi_1, \xi_2) \in \mathbf{N} \times (\ell^{-1}\mathbf{N})$ with ξ_1 sufficiently large. Since $\nu \geq 0$, the previous inequality holds for all $\xi \in \mathbf{Z} \times \ell^{-1}\mathbf{Z}$ with $|\xi_1|$ sufficiently large.

Now, since $|\xi| \sim \nu\xi_1^2$ on the set where the above inequality is not satisfied, this in turn implies that,

$$\left| \xi_2 - \nu\xi_1^2 + \kappa - \frac{\kappa'}{\xi_1^2} \right| \geq \frac{\nu}{\ell\,|\xi|^{(2+\delta)/2}}, \tag{5.30}$$

for all $\xi \in \mathbf{Z} \times (\ell^{-1}\mathbf{Z})$ with $|\xi_1|$ sufficiently large.

Similarly, we obtain that

$$\left| \xi_2 - \nu\xi_1^2 + \kappa - \frac{\kappa'}{\xi_1^2} \right| \geq \frac{\sqrt{\nu}\,|\xi_1|}{\ell\,|\xi|^{(3+\delta)/2}}, \tag{5.31}$$

for $|\xi_1|$ sufficiently large.

To use these inequalities, we take the Fourier transform of (5.29):

$$\Big(\xi_2 - \nu\xi_1^2 + \kappa - \frac{\kappa'\eta(\xi_1)}{\xi_1^2}\Big)\widehat{Z_cU}(\xi) =: \widehat{f}(\xi).$$

A key point is that Z_cU is doubly periodic. Thus, if ξ belongs to the support of the Fourier transform of Z_cU, then $\xi \in \mathbf{Z} \times (\ell^{-1}\mathbf{Z})$. Therefore, it follows from (5.30) and (5.31) that,

$$Z_cU \in H^{s+1-\frac{\delta}{2}}(\mathbf{T}^2), \quad \partial_{x_1}Z_cU \in H^{s+\frac{1}{2}-\frac{\delta}{2}}(\mathbf{T}^2).$$

It follows that

$$U \in H^{s+1-\frac{\delta}{2}}(\mathbf{T}^2), \quad \partial_{x_1}U \in H^{s+\frac{1}{2}-\frac{\delta}{2}}(\mathbf{T}^2).$$

In view of (5.27) and (5.28), we end up with

$$\left(\chi^{-1}\right)^{*}u \in H^{s+1-\frac{\delta}{2}}(\mathbf{T}^2), \tag{5.32}$$

$$\partial_{x_1}(\left(\chi^{-1}\right)^{*}u) \in H^{s+\frac{1}{2}-\frac{\delta}{2}}(\mathbf{T}^2). \tag{5.33}$$

Direclty from (5.32), by using Theorem 5.20, we obtain

$$u \in H^{s+1-\frac{\delta}{2}}(\mathbf{T}^2). \tag{5.34}$$

We next claim that

$$T_V \cdot \nabla u \in H^{s+\frac{1}{2}-\frac{\delta}{2}}(\mathbf{T}^2). \tag{5.35}$$

To prove (5.35), we first note that Theorem 5.20 implies that it is enough to prove that

$$\left(\chi^{-1}\right)^{*}\left(T_V \cdot \nabla u\right) \in H^{s+\frac{1}{2}-\frac{\delta}{2}}(\mathbf{T}^2).$$

To prove this result, we shall apply our second theorem about paracomposition operators. Indeed, define the symbol a by

$$a^*(\chi(x),\eta) = V(x)\cdot\left(i\,{}^t\chi'(x)\eta\right).$$

Theorem 5.21 implies that

$$\left(\chi^{-1}\right)^{*}T_V\cdot\nabla - T_{a^*}\left(\chi^{-1}\right)^{*} \quad \text{is of order } \leq 0.$$

Consequently, in view of (5.34), we obtain

$$\left(\chi^{-1}\right)^{*}T_V\cdot\nabla u - T_{a^*}\left(\chi^{-1}\right)^{*}u \in H^{s+1-\frac{\delta}{2}}(\mathbf{T}^2). \tag{5.36}$$

Now, directly from the definition of χ (see §3.1), we compute that

$$a^*(\chi(x),\eta) = i\alpha(x)\xi_1 \quad \text{with} \quad \alpha(x) = V_1(x)\left(1+\partial_{x_1}\tilde{d}(\chi_1(x))\right).$$

Therefore, (5.33) implies that

$$T_{a^*}\left(\chi^{-1}\right)^{*}u \in H^{s+\frac{1}{2}-\frac{\delta}{2}}(\mathbf{T}^2).$$

Consequently, the claim (5.35) follows from (5.36)

Now recall that we have proved that (cf (5.8))

$$\sigma + T_{\mathfrak{a}^{-1}}T_V\cdot\nabla u \in H^{2s-4}(\mathbf{T}^2). \tag{5.37}$$

Since $T_{\mathfrak{a}^{-1}}$ is of order ≤ 0, by using (5.35) we obtain

$$\sigma \in H^{2s-4}(\mathbf{T}^2) + H^{s+\frac{1}{2}-\frac{\delta}{2}}(\mathbf{T}^2),$$

and hence

$$\sigma \in H^{s+\frac{1}{2}-\frac{\delta}{2}}(\mathbf{T}^2). \tag{5.38}$$

Since $T_{\mathfrak{b}}$ is of order ≤ 0, this yields

$$T_{\mathfrak{b}}\sigma \in H^{s+\frac{1}{2}-\frac{\delta}{2}}(\mathbf{T}^2). \tag{5.39}$$

Writing $\psi = u + T_{\mathfrak{b}}\sigma$ (by definition of u), from (5.34) and (5.39) we deduce that

$$\psi \in H^{s+\frac{1}{2}-\frac{\delta}{2}}(\mathbf{T}^2).$$

This completes the proof of Theorem 5.1 and hence of Theorem 2.5. □

5.9 Preparation

We have proved that there exist a change of variables $x \mapsto \chi(x)$ and two zero order symbols $A = A(x,\xi)$ and $B(x,\xi)$ such that

$$\Big(|D_x| + \nu\partial_{x_1}^2 + T_A\partial_{x_1} + T_B\Big)\big(\chi^{-1}\big)^* u = f \in H^{s+2}(\mathbf{T}^2). \tag{5.40}$$

We want to prove Proposition 5.27 which asserts that it is possible to conjugate (5.40) to a constant coefficient equation. Since the symbols A and B depend on the frequency variable, one more reduction is needed.

In this paragraph we shall prove the following preliminary result towards the proof of Proposition 5.27.

Proposition 5.28. *There exist five functions*

$$a_j = a_j(x) \in C^{s-6-j}(\mathbf{T}^2) \qquad (0 \leq j \leq 4),$$

where

$$a_j \text{ is odd in } x_1 \text{ for } j \in \{0,2,4\}, \quad a_j \text{ is even in } x_1 \text{ for } j \in \{1,3\},$$

such that

$$\left(-i\partial_{x_2} + \nu\partial_{x_1}^2 + \sum_{0\leq j\leq 4} T_{a_j}\partial_{x_1}^{1-j}\right) U \in H^{s+2}(\mathbf{T}^2),$$

where recall that $U = j_+(D_x)((\chi^{-1})^* u)$.

To prove this result, we begin with the following localization lemma.

Lemma 5.29. *Let* $A = A(x,\xi)$ *and* $B = B(x,\xi)$ *be as in* (5.20). *Then,*

$$\Big(|D_x| + \nu\partial_{x_1}^2 + T_A\partial_{x_1} + T_B\Big)U \in H^{s+2}(\mathbf{T}^2). \tag{5.41}$$

Proof. This follows from Corollary 5.22 and Proposition 5.25. Indeed, since $\jmath_+$ is positively homogeneous of degree 0, it is a zero-order symbol. According to Theorem 4.6 (applied with $a = \jmath_+(\xi)$, $b = A(x,\xi)i\xi_1 + B(x,\xi)$ and $(m, m', \rho) = (0, 1, 3)$), then,

$$\begin{aligned}&j_+(D_x)\Big(|D_x| + \nu\partial_{x_1}^2 + T_A\partial_{x_1} + T_B\Big)\big((\chi^{-1})^* u\big)\\&= \Big(|D_x| + \nu\partial_{x_1}^2 + T_A\partial_{x_1} + T_B\Big)U + \sum_{1\le|\alpha|\le 2} \frac{1}{i^\alpha \alpha!} T_{\partial_\xi^\alpha \jmath_+(\xi)\partial_x^\alpha b(x,\xi)}\big((\chi^{-1})^* u\big) + f,\end{aligned}$$

with $f \in H^{s+2}(\mathbf{T}^2)$. Corollary 5.22 implies that the left hand side belongs to $H^{s+2}(\mathbf{T}^2)$. As regards the second term in the right hand side, observe that

$$|\xi_2| \geq \frac{3}{4}|\xi_1| \Rightarrow \partial_\xi \jmath_+(\xi) = 0.$$

Moreover $\partial_\xi^\alpha \jmath_+(\xi)\partial_x^\alpha b(x,\xi)$ is of order ≤ 0 in ξ. Hence, by means of a simple symbolic calculus argument, it follows from Proposition 5.25 that

$$T_{\partial_\xi^\alpha \jmath_+(\xi)\partial_x^\alpha b(x,\xi)}\big((\chi^{-1})^* u\big) \in H^{s+2}(\mathbf{T}^2).$$

This proves the lemma. □

We are now in position to transform the equation. To clarify the articulation of the proof, we proceed step by step. We first prove that

i) $|D_x|U$ may be replaced by $-i\partial_{x_2}U$ ($-i\partial_{x_2}$ is the Fourier multiplier with symbol $+\xi_2$). This point essentially follows from the fact that $|\xi| \sim \xi_2$ on the support of $\jmath_+(\xi)$.

ii) One may replace the symbols A and B by a couple of symbols which are symmetric with respect to $\{\xi_2 = 0\}$ and vanish for $|\xi_2| \leq |\xi_1|/5$. The idea is that, since $\widehat{U}(\xi) = 0$ for $\xi_2 \leq |\xi_1|/2$, for any $c < 1/2$ one may freely change the values of $A(x,\xi)$ and $B(x,\xi)$ for $\xi_2 \leq c|\xi_1|$.

Lemma 5.30. *There exists two symbols $\tilde{A} \in \Gamma_{s-6}^0(\mathbf{T}^2)$, $\tilde{B} \in \Sigma_{s-6}^0(\mathbf{T}^2)$ such that*

$$\Big(-i\partial_{x_2} + \nu\partial_{x_1}^2 + T_{\tilde{A}}\partial_{x_1} + T_{\tilde{B}}\Big)U \in H^{s+2}(\mathbf{T}^2), \tag{5.42}$$

and such that

i) $\tilde{A}$ *is homogeneous of degree* 0 *in* ξ*;* $\tilde{B} = \tilde{B}_0 + \tilde{B}_{-1}$ *where* $\tilde{B}_\ell$ *is homogeneous of degree* ℓ *in* ξ*;*

ii) $\tilde{A}(x^\star, \xi^\star) = -\tilde{A}(x,\xi)$ *and* $\tilde{B}(x^\star,\xi^\star) = \tilde{B}(x,\xi)$*;*

iii) $\tilde{A}(x,\xi_1,-\xi_2) = \tilde{A}(x,\xi_1,\xi_2)$ *and* $\tilde{B}(x,\xi_1,-\xi_2) = \tilde{B}(x,\xi_1,\xi_2)$*;*

iv) $\tilde{A}(x,\xi) = 0 = \tilde{B}(x,\xi)$ *for* $|\xi_2| \leq |\xi_1|/5$.

Proof. The proof depends on Lemma 5.29 and the fact that the Fourier multiplier $\jmath_+(D_x)$ is essentially a projection operator. Namely, we make use of a C^∞ function J' satisfying $0 \le J' \le 1$ and such that,

$$J'(s) = 0 \quad \text{for } s \le 0.7, \qquad J'(s) = 1 \quad \text{for } s \ge 0.8,$$

and set

$$\jmath'_\pm(\xi) = J'\left(\frac{|\xi| \pm \xi_2}{2\,|\xi|}\right).$$

Then $\jmath'_\pm(\xi) = 0$ for $|\xi_2| \le |\xi_1|/5$, and

$$\jmath'_+(\xi)\jmath_+(\xi) = \jmath_+(\xi), \quad \jmath'_-(\xi)\jmath_+(\xi) = 0. \tag{5.43}$$

With $A = A(x,\xi)$ and $B = B(x,\xi)$ as in (5.20), set

$$\begin{aligned}
\tilde{A}(x,\xi_1,\xi_2) &= \jmath'_+(\xi)\left(A(x,\xi_1,\xi_2) - \frac{i\xi_1}{|\xi| + |\xi_2|}\right)\\
&\quad + \jmath'_-(\xi)\left(A(x,\xi_1,-\xi_2) - \frac{i\xi_1}{|\xi| + |\xi_2|}\right),\\
\tilde{B}(x,\xi_1,\xi_2) &= \jmath'_+(\xi)B(x,\xi_1,\xi_2) + \jmath'_-(\xi)B(x,\xi_1,-\xi_2).
\end{aligned}$$

Note that these symbols satisfy the desired properties.

On the symbol level, we have

$$|\xi| = |\xi_2| + \frac{\xi_1^2}{|\xi| + |\xi_2|} = |\xi_2| - \frac{i\xi_1}{|\xi| + |\xi_2|} i\xi_1.$$

On the other hand, by the very definition of paradifferential operators, for any couple of symbols $c_1 = c_1(x,\xi)$ and $c_2 = c_2(\xi)$ depending only on ξ, we have

$$T_{c_1}T_{c_2} = T_{c_1c_2}.$$

Therefore, by means of (5.43) we easily check that

$$\left(-i\partial_{x_2} + \nu\partial_{x_1}^2 + T_{\tilde{A}}\partial_{x_1} + T_{\tilde{B}}\right)U = \left(|D_x| + \nu\partial_{x_1}^2 + T_A\partial_{x_1} + T_B\right)U.$$

The desired result then follows from (5.41) □

To prepare for the next transformation, we need a calculus lemma to handle commutators of the form $[T_p, \partial_{x_1}^{-j}]$. Note that $\eta(\xi_1)(i\xi_1)^{-j}$ does not belong to our symbol classes. However, we have the following result.

Proposition 5.31. *Let $p \in \Gamma^0_4(\mathbf{T}^2)$ and $v \in H^{-\infty}(\mathbf{T}^2)$ be such that*

$$\partial_{x_1}^{-5} v \in H^{s+2}(\mathbf{T}^2).$$

If

$$\int_{-\pi}^{\pi} T_p v \, dx_1 = 0 = \int_{-\pi}^{\pi} v \, dx_1, \tag{5.44}$$

then

$$\partial_{x_1}^{-1} T_p v = T_p \partial_{x_1}^{-1} v - T_{\partial_{x_1} p} \partial_{x_1}^{-2} v + T_{\partial_{x_1}^2 p} \partial_{x_1}^{-3} v - T_{\partial_{x_1}^3 p} \partial_{x_1}^{-4} v + f,$$

where $f \in H^{s+2}(\mathbf{T}^2)$.

Proof. We begin by noticing that (5.44) implies that

$$\partial_{x_1}^0 T_p v = T_p v, \quad \partial_{x_1}^0 v = v,$$

and hence

$$\partial_{x_1} \left(\partial_{x_1}^{-1} T_p v - T_p \partial_{x_1}^{-1} v \right) = T_p v - T_{\partial_{x_1} p} \partial_{x_1}^{-1} v - T_p v = -T_{\partial_{x_1} p} \partial_{x_1}^{-1} v.$$

Since $u = \partial_{x_1} U$ implies $U = \partial_{x_1}^{-1} u$, this yields

$$\partial_{x_1}^{-1} T_p v - T_p \partial_{x_1}^{-1} v = -\partial_{x_1}^{-1} T_{\partial_{x_1} p} \partial_{x_1}^{-1} v. \tag{5.45}$$

To repeat this argument we first note that, by definition of $\partial_{x_1}^{-1}$, we have

$$\int_{-\pi}^{\pi} \partial_{x_1}^{-1} v \, dx_1 = 0.$$

On the other hand,

$$\begin{aligned} \int_{-\pi}^{\pi} T_{\partial_{x_1} p} \partial_{x_1}^{-1} v \, dx_1 &= \int_{-\pi}^{\pi} \partial_{x_1} \left(T_p \partial_{x_1}^{-1} v \right) - T_p \partial_{x_1}^0 v \, dx_1 \\ &= \int_{-\pi}^{\pi} \partial_{x_1} \left(T_p \partial_{x_1}^{-1} v \right) \, dx_1 - \int_{-\pi}^{\pi} T_p v \, dx_1 \\ &= 0, \end{aligned}$$

by periodicity in x_1 and (5.44). We can thus apply (5.45) with (p, v) replaced by $(\partial_{x_1} p, \partial_{x_1}^{-1} v)$ to obtain

$$\partial_{x_1}^{-1} T_{\partial_{x_1} p} \partial_{x_1}^{-1} v - T_{\partial_{x_1} p} \partial_{x_1}^{-2} v = -\partial_{x_1}^{-1} T_{\partial_{x_1}^2 p} \partial_{x_1}^{-2} v. \tag{5.46}$$

By inserting this result in (5.45) we obtain

$$\partial_{x_1}^{-1} T_p v = T_p \partial_{x_1}^{-1} v - T_{\partial_{x_1} p} \partial_{x_1}^{-2} v + \partial_{x_1}^{-1} T_{\partial_{x_1}^2 p} \partial_{x_1}^{-2} v.$$

By repeating this reasoning we end up with

$$\partial_{x_1}^{-1} T_p v = T_p \partial_{x_1}^{-1} v - T_{\partial_{x_1} p} \partial_{x_1}^{-2} v + T_{\partial_{x_1}^2 p} \partial_{x_1}^{-3} v - T_{\partial_{x_1}^3 p} \partial_{x_1}^{-4} v + f,$$

where

$$f = T_{\partial_{x_1}^4 p} \partial_{x_1}^{-5} v - \partial_{x_1}^{-1} T_{\partial_{x_1}^4 p} \partial_{x_1}^{-5} v.$$

By assumption $\partial_{x_1}^{-5} v \in H^{s+2}(\mathbf{T}^2)$ and $\partial_{x_1}^4 p \in \Gamma_0^0(\mathbf{T}^2)$ so that $T_{\partial_{x_1}^4 p}$ is of order ≤ 0. Therefore we obtain $f \in H^{s+2}(\mathbf{T}^2)$, which concludes the proof. □

We have an analogous result for commutators $[T_p, \partial_{x_1}^{-j}]$ for $2 \le j \le 4$.

Corollary 5.32. *Let* $p \in \Gamma_4^0(\mathbf{T}^2)$ *and* $v \in H^{-\infty}(\mathbf{T}^2)$ *be such that* $\partial_{x_1}^{-5} v \in H^{s+2}(\mathbf{T}^2)$. *If*

$$\int_{-\pi}^{\pi} T_p v \, dx_1 = 0 = \int_{-\pi}^{\pi} v \, dx_1,$$

then

$$\begin{aligned} \partial_{x_1}^{-2} T_p v &= T_p \partial_{x_1}^{-2} v - T_{\partial_{x_1} p} \partial_{x_1}^{-3} v + T_{\partial_{x_1}^2 p} \partial_{x_1}^{-4} v + f_2, \\ \partial_{x_1}^{-3} T_p v &= T_p \partial_{x_1}^{-3} v - T_{\partial_{x_1} p} \partial_{x_1}^{-4} v + f_3, \\ \partial_{x_1}^{-4} T_p v &= T_p \partial_{x_1}^{-4} v + f_4, \end{aligned}$$

where $f_2, f_3, f_4 \in H^{s+2}(\mathbf{T}^2)$.

Proof. This follows from the previous Proposition. □

An important remark for what follows is that ∂_{x_1} and ∂_{x_2} do not have the same weight. Roughly speaking, the form of the equation (5.40) indicates that

$$\nu \partial_{x_1}^2 \sim |D_x| \sim |\partial_{x_2}| \, .$$

In particular, we shall make extensive use of

$$\nu^{-1} \partial_{x_1}^{-2} \sim |D_x|^{-1} \, .$$

The following lemma gives this statement a rigorous meaning.

Lemma 5.33. *There holds* $\partial_{x_1}^{-2} U \in H^{s+1}(\mathbf{T}^2)$ *and* $\partial_{x_1}^{-4} U \in H^{s+2}(\mathbf{T}^2)$.

Proof. Recall that $A(x^\star, \xi^\star) = -A(x, \xi)$ and that U is odd in x_1 and 2π-periodic in x_1, so we have

$$\int_{-\pi}^{\pi} T_A \partial_{x_1} U \, dx_1 = 0, \quad \int_{-\pi}^{\pi} \partial_{x_1} U \, dx_1 = 0, \quad \int_{-\pi}^{\pi} U \, dx_1 = 0. \tag{5.47}$$

Since

$$|D_x| \, U + \nu \partial_{x_1}^2 U + T_A \partial_{x_1} U + T_B U \in H^{s+2}(\mathbf{T}^2),$$

by applying $\Lambda^{-1} \partial_{x_1}^{-2}$ with $\Lambda^{-1} = T_{|\xi|^{-1}}$, we have

$$\partial_{x_1}^{-2} U = -\nu \Lambda^{-1} U - \Lambda^{-1} \partial_{x_1}^{-2} (T_A \partial_{x_1} U) - \Lambda^{-1} \partial_{x_1}^{-2} (T_B U) + F,$$

where $F \in H^{s+2}(\mathbf{T}^2)$. The first term and the third term in the right hand side obviously belong to $H^{s+1}(\mathbf{T}^2)$. Moving to the second term in the right-hand side, in view of (5.47), the argument establishing (5.45) also gives

$$\partial_{x_1}^{-2} T_A \partial_{x_1} U = \partial_{x_1}^{-1} T_A U - \partial_{x_1}^{-1} T_{\partial_{x_1} A} U.$$

Hence, using that $\partial_{x_1}^{-1}, T_A$ and $T_{\partial_{x_1} A}$ are of order ≤ 0, we have that

$$\partial_{x_1}^{-2} T_A \partial_{x_1} U \in H^s(\mathbf{T}^2),$$

so that $\Lambda^{-1}\partial_{x_1}^{-2}(T_A\partial_{x_1}U) \in H^{s+1}(\mathbf{T}^2)$ and hence

$$\partial_{x_1}^{-2} U \in H^{s+1}(\mathbf{T}^2). \tag{5.48}$$

To study $\partial_{x_1}^{-4}U$ we start from

$$\begin{aligned}\partial_{x_1}^{-4}U = -\nu\Lambda^{-1}\partial_{x_1}^{-2}U - \Lambda^{-1}\partial_{x_1}^{-4}(T_A\partial_{x_1}U)\\ - \Lambda^{-1}\partial_{x_1}^{-4}(T_B U) + \partial_{x_1}^{-2}F,\end{aligned}$$

We have just proved that the first term in the right hand side belongs to $H^{s+2}(\mathbf{T}^2)$. With regards to the second term we use the third identity in Corollary 5.32 to obtain

$$\partial_{x_1}^{-4}(T_A\partial_{x_1}U) - T_A\partial_{x_1}^{-3}U \in H^{s+2}(\mathbf{T}^2).$$

On the other hand, by symbolic calculus, $\Lambda^{-1}T_A - T_A\Lambda^{-1}$ is of order ≤ -2. Hence,

$$\Lambda^{-1}\partial_{x_1}^{-4}(T_A\partial_{x_1}U) - T_A\Lambda^{-1}\partial_{x_1}^{-3}U \in H^{s+2}(\mathbf{T}^2).$$

In view of (5.48) this yields

$$\Lambda^{-1}\partial_{x_1}^{-4}(T_A\partial_{x_1}U) \in H^{s+2}(\mathbf{T}^2).$$

Similarly we obtain that $\Lambda^{-1}\partial_{x_1}^{-4}(T_B U) \in H^{s+2}(\mathbf{T}^2)$. We thus end up with

$$\partial_{x_1}^{-4}U \in H^{s+2}(\mathbf{T}^2),$$

which concludes the proof. □

The following definition is helpful for what follows.

Definition 5.34. *We say that an operator R is of anisotropic order ≤ -2 if R is of the form*

$$R = R_0\Lambda^{-2} + R_1\Lambda^{-1}\partial_{x_1}^{-2} + R_2\partial_{x_1}^{-4},$$

where R_0, R_1 and R_2 are operators of order ≤ 0 and

$$\Lambda^{-1} = T_{|\xi|^{-1}}, \quad \Lambda^{-2} = T_{|\xi|^{-2}}.$$

It follows from the previous lemma that operators of anisotropic order ≤ -2 may be seen as operators of order ≤ -2. Namely, the previous lemma implies the following result.

Lemma 5.35. *If R is of anisotropic order ≤ -2, then $RU \in H^{s+2}(\mathbf{T}^2)$.*

With these preliminaries established, to prove Proposition 5.28 the key point is a decomposition of zero-order symbols. We want to decompose zero-order operators as sums of the form

$$\sum_{0\le j\le 4} T_{a_j}\partial_{x_1}^{-j} + R,$$

where T_{a_j} are paraproducts ($a_j = a_j(x)$ does not depend on ξ) and R is of anisotropic order ≤ -2 plus an admissible remainder. More generally, we consider below symbols of order $-2 \le m \le 0$ and not only zero-order symbols.

Lemma 5.36. *Let $m \in \{0,1,2\}$ and $\rho \ge 0$. Let $S \in \Gamma_\rho^{-m}(\mathbf{T}^2)$ be an homogeneous symbol of degree $-m$ in ξ such that*

$$S(x,\xi_1,-\xi_2) = S(x,\xi_1,\xi_2),$$

and such that, for some positive constant c,

$$|\xi_2| \le c\,|\xi_1| \Rightarrow S(x,\xi) = 0.$$

Then, for all v whose spectrum is included in the semi-cone $\{\xi_2 \ge c\,|\xi_1|\}$,

$$T_{S(x,\xi)}\partial_{x_1}v = \sum_{j=2m}^{4} T_{S_j(x)}\partial_{x_1}^{1-j}v + Q(-i\partial_{x_2} + \nu\partial_{x_1}^2)v + Rv, \tag{5.49}$$

where R is of anisotropic order ≤ -2,

$$S_j(x) = \frac{1}{i^j\nu^j j!}(\partial_{\xi_1}^j S)(x,0,1), \tag{5.50}$$

and

$$Q = \sum_{k=2m+1}^{4} T_{q_k(x,\xi)}\partial_{x_1}^{1-k},$$

where $q_k \in \Gamma_\rho^{-1}(\mathbf{T}^2)$ for $1 \le k \le 4$ is explicitly defined in (5.55) *below and satisfies*

$$q_k(x,\xi_1,-\xi_2) = q_k(x,\xi_1,\xi_2), \tag{5.51}$$

and

$$|\xi_2| \le \frac{c}{2}\,|\xi_1| \Rightarrow q_k(x,\xi) = 0. \tag{5.52}$$

Remark 5.37. This is a variant of the decomposition used in [22]. The main difference is that, having performed the reduction to the case where $\xi_2 \ge |\xi_1|/2$, we do not need to consider the so-called elementary operators in [22]. Hence we obtain a decomposition where the S_j's do not depend on ξ.

Proof. The proof is based on the following simple observation: $\xi \mapsto \xi_1$ is transverse to the characteristic variety. We prove Lemma 5.36 for $m = 0$.

Let J_c be a real-valued function, homogeneous of degree 0 such that $J_c(\xi_1, \xi_2) = J_c(\xi_1, -\xi_2)$ and

$$J_c(\xi) = 0 \quad \text{for } |\xi_2| \leq \frac{c}{2}\,|\xi_1|\,, \qquad J_c(\xi) = 1 \quad \text{for } |\xi_2| \geq c\,|\xi_1|$$

(so that $J_c(\xi)S(x,\xi) = S(x,\xi)$ and $J_c(D_x)v = v$). We shall prove that

$$T_{S(x,\xi)}\partial_{x_1}^0 = \sum_{j=0}^{4} T_{S_j(x)}\partial_{x_1}^{-j} J_c + \sum_{k=1}^{4} T_{q_k(x,\xi)}\partial_{x_1}^{-k}(|\partial_{x_2}| + \nu\partial_{x_1}^2) + R', \tag{5.53}$$

where S_j, q_k are as in the statement of the lemma and R' is such that the operator $R'\partial_{x_1}$ is of anisotropic order ≤ -2. This yields the desired result (5.49) since $J_c v = v$ and $|\partial_{x_2}|\, v = -i\partial_{x_2} v$ by assumption on the spectrum of$v$.

For $m = 0$, S is an homogeneous symbol of degree 0 in ξ. By the symmetry hypothesis $S(x, \xi_1, \xi_2) = S(x, \xi_1, -\xi_2)$, we can write $S(x,\xi)$ as

$$S(x,\xi) = S\left(x, \frac{\xi_1}{|\xi_2|}, 1\right),$$

(if $\xi_2 = 0$ then $S(x,\xi) = 0$ by assumption) so we have

$$S(x,\xi) = \sum_{j=0}^{4} \frac{1}{i^j j!}(\partial_{\xi_1}^j \tilde{S})(x,0,1)\left(i\frac{\xi_1}{|\xi_2|}\right)^j + r\left(x, \frac{\xi_1}{|\xi_2|}\right)\left(i\frac{\xi_1}{|\xi_2|}\right)^5, \tag{5.54}$$

where r is given by Taylor's formula.

Next, by setting

$$\mathcal{L}(\xi) := |\xi_2| - \nu\xi_1^2,$$

we claim that, for $1 \leq k \leq 4$, there exists a Fourier multiplier $Q_k(D_x)$ of order ≤ -1 such that,

$$J_c(\xi)\, i\xi_1 \left(i\frac{\xi_1}{|\xi_2|}\right)^k = -\frac{J_c(\xi)}{i^{k-1}\nu^k \xi_1^{k-1}} + Q_k(\xi)\mathcal{L}(\xi).$$

To see this, write

$$\frac{\xi_1^2}{|\xi_2|} = -\frac{\mathcal{L}(\xi)}{\nu\,|\xi_2|} + \frac{1}{\nu}, \quad \frac{\xi_1^4}{|\xi_2|^2} = \left(-\frac{\mathcal{L}(\xi)}{\nu\,|\xi_2|} + \frac{1}{\nu}\right)^2, \quad \frac{\xi_1^6}{|\xi_2|^3} = \left(-\frac{\mathcal{L}(\xi)}{\nu\,|\xi_2|} + \frac{1}{\nu}\right)^3,$$

to obtain the desired identities with $Q_j(\xi) = J_c(\xi)\tilde{Q}_j(\xi)$ where

$$\tilde{Q}_1(\xi) = \frac{1}{\nu\,|\xi_2|}, \qquad \tilde{Q}_3(\xi) = -\frac{\nu\,|\xi_2|\,\xi_1^2 + |\xi_2|^2 + \nu^2\xi_1^4}{\nu^3\xi_1^2\,|\xi_2|^3},$$

$$\tilde{Q}_2(\xi) = -\frac{|\xi_2| + \nu\xi_1^2}{i\nu^2\,|\xi_2|^2\,\xi_1}, \quad \tilde{Q}_4(\xi) = -\frac{i\left(c_1\,|\xi_2|^3 + c_2\,|\xi|^2\,\xi_1^2 + c_3\,|\xi_2|\,\xi_1^4 + c_4\xi_1^6\right)}{\nu^4\xi_1^3\,|\xi_2|^4},$$

where $c_1 := 3 - 6\nu + 4\nu^2$, $c_2 := 3\nu + 6\nu^2 - 8\nu^3$, $c_3 := 3\nu^2 + 4\nu^4$ and $c_4 := \nu^3$. Similarly, we have

$$i\xi_1 \left(i \frac{\xi_1}{|\xi_2|} \right)^5 = -\frac{1}{\nu^3 |\xi_2|^2} + \tilde{Q}_5(\xi)\mathcal{L}(\xi) \text{ with } \tilde{Q}_5(\xi) := \frac{|\xi_2|^2 + 4\nu |\xi_2| \xi_1^2 + \nu^2 \xi_1^4}{\nu^3 |\xi_2|^5}.$$

Our analysis of (5.54) is complete; by inserting the previous identities in (5.54) premultiplied by $J_c(\xi)\eta(\xi_1)i\xi_1$ and next by dividing by $i\xi_1$, we obtain the desired decomposition (5.53) with $q_k(x,\xi) = J_c(\xi)\tilde{q}_k(x,\xi)$ where

$$\begin{aligned}
\tilde{q}_1(x,\xi) =& \frac{S_1(x)}{|\xi_2|} - \frac{\nu S_3(x)}{|\xi_2|^2} \\
&+ i\xi_1 \left(\frac{i\nu^2 S_3(x)\xi_1}{|\xi_2|^3} - \frac{\nu S_2(x)}{|\xi_2|^2} - \frac{(c_3 |\xi_2| + c_4 \xi_1^2) S_4(x)}{|\xi_2|^4} \right) \\
&+ r\left(x, \frac{\xi_1}{|\xi_2|} \right) \tilde{Q}_5(\xi), \\
\tilde{q}_2(x,\xi) =& \frac{-S_2(x)}{\nu^2 |\xi_2|} - i \frac{c_2 S_4}{|\xi_2|^2}, \\
\tilde{q}_3(x,\xi) =& \frac{S_3(x)}{\nu^3 |\xi_2|}, \\
\tilde{q}_4(x,\xi) =& \frac{-c_1 S_4(x)}{\nu^4 |\xi_2|}.
\end{aligned} \tag{5.55}$$

Note that each term making up $q_k(x,\xi)$ is well-defined and C^∞ for $\xi \neq 0$ and homogeneous of degree -1 or -2 or -3 in ξ, so $q_k \in \Gamma_\rho^{-1}(\mathbf{T}^2)$. □

We are now prepared to conclude the proof of Proposition 5.28. We want to prove that there exist five functions

$$a_j = a_j(x) \in C^{s-6-j}(\mathbf{T}^2) \qquad (0 \le j \le 4),$$

where

$$a_j \text{ is odd in } x_1 \text{ for } j \in \{0,2,4\}, \quad a_j \text{ is even in } x_1 \text{ for } j \in \{1,3\},$$

such that

$$\left(-i\partial_{x_2} + \nu\partial_{x_1}^2 + \sum_{0 \le j \le 4} T_{a_j} \partial_{x_1}^{1-j} \right) U \in H^{s+2}(\mathbf{T}^2). \tag{5.56}$$

To this end, since $\tilde{A}$ and $\tilde{B}$ satisfy properties iii) and iv) in Lemma 5.30, since $U = \partial_{x_1}^0 U$ and since the spectrum of U is contained in the semi-cone $\{\xi_2 \ge \frac{3}{4}|\xi_1|\}$, we can use the above symbol-decomposition process to obtain for U an equation of the form

$$(I + Q)\left(-i\partial_{x_2} U + \nu\partial_{x_1}^2 U \right) + \sum_{0 \le j \le 4} T_{\alpha_j} \partial_{x_1}^{1-j} U = f \in H^{s+2}(\mathbf{T}^2),$$

where $\alpha_j \in C^{s-6}(\mathbf{T}^2)$ and

$$Q = \sum_{k=1}^{4} T_{q_k(x,\xi)} \partial_{x_1}^{1-k},$$

where $q_k \in \Gamma^{-1}_{s-6}(\mathbf{T}^2)$.

Write

$$(I+Q)\left(-i\partial_{x_2} U + \nu \partial_{x_1}^2 U + \sum_{0\le j\le 4} T_{\alpha_j} \partial_{x_1}^{1-j} U\right) - Q \sum_{0\le j\le 4} T_{\alpha_j} \partial_{x_1}^{1-j} U = f.$$

Now, by using Proposition 5.31 and its corollary 5.32, notice that we can write the term $Q\sum_{0\le j\le 4} T_{\alpha_j}\partial_{x_1}^{1-j}U$ under the form

$$\sum\sum\sum (-1)^{\ell} T_{q_k} T_{\partial_{x_1}^{\ell}\alpha_j} \partial_{x_1}^{2-j-k-\ell} U + F,$$

where $F \in H^{s+2}(\mathbf{T}^2)$ where the sum is taken over indices k, j, ℓ such that $1 \le k \le 4$, $0 \le j \le 4$ and

$$j+k+\ell \le 3.$$

Indeed, for those indices such that $j+k+\ell \ge 4$ the operator $T_{q_k} T_{\partial_{x_1}^{\ell}\alpha_j} \partial_{x_1}^{2-j-k-\ell}$ is of anisotropic index ≤ -2 and hence $T_{q_k} T_{\partial_{x_1}^{\ell}\alpha_j} \partial_{x_1}^{2-j-k-\ell} U \in H^{s+2}(\mathbf{T}^2)$, so that these terms can be handled as source terms. Next, noticing that $T_{q_k} T_{\partial_{x_1}^{\ell}\alpha_j} - T_{q_k \partial_{x_1}^{\ell}\alpha_j}$ is order less than -3, this implies that we have

$$Q \sum_{0\le j\le 4} T_{\alpha_j} \partial_{x_1}^{1-j} U = \sum_{0\le p\le 4} T_{\mathcal{S}_p} \partial_{x_1}^{1-p}.$$

for some symbols $\mathcal{S}_p$ of order -1 in ξ, with regularity $s-8$ in x and satisfying the spectral assumptions in Lemma 5.36. As a consequence, by applying Lemma 5.36 we obtain

$$Q \sum_{0\le j\le 4} T_{\alpha_j} \partial_{x_1}^{1-j} U = \sum_{2\le k\le 4} T_{\beta_k(x)} \partial_{x_1}^{1-k} U + Q'\left(-i\partial_{x_2} + \nu \partial_{x_1}^2\right) U + R'U,$$

where $\beta_k \in C^{s-8}(\mathbf{T}^2)$, R' is of anisotropic order ≤ -2 and Q' is of the form

$$Q' = \sum_{k=3}^{4} T_{q'_k(x,\xi)} \partial_{x_1}^{1-k},$$

where $q'_k(x,\xi)$ is of order -1 in ξ (and regularity C^{s-8} in x). Then

$$\begin{aligned}(I+Q-Q')&\left(-i\partial_{x_2} + \nu \partial_{x_1}^2 + \sum_{0\le j\le 4} T_{\alpha_j} \partial_{x_1}^{1-j} - \sum_{2\le k\le 4} T_{\beta_k(x)} \partial_{x_1}^{1-k}\right) U \\ &+ (Q-Q') \sum_{2\le k\le 4} T_{\beta_k(x)} \partial_{x_1}^{1-k} U + Q' \sum_{0\le j\le 4} T_{\alpha_j} \partial_{x_1}^{1-j} \in H^{s+2}(\mathbf{T}^2).\end{aligned}$$

Again, one has

$$(Q-Q')\sum_{2\le k\le 4}T_{\beta_k(x)}\partial_{x_1}^{1-k}U+Q'\sum_{0\le j\le 4}T_{\alpha_j}\partial_{x_1}^{1-j}=T_{\gamma_4(x)}\partial_{x_1}^{-3}+R''U.$$

Now $(Q-Q')T_{\gamma_4}\partial_{x_1}^{-3}$ is of anisotropic order ≤ -2. This yields

$$(I+\mathcal{Q})\left(-i\partial_{x_2}U+\nu\partial_{x_1}^2U+\sum_{0\le j\le 4}T_{a_j}\partial_{x_1}^{1-j}U\right)\in H^{s+2}(\mathbf{T}^2),$$

where $\mathcal{Q}=Q-Q'$ and

$$a_0=\alpha_0,\ a_1=\alpha_1,\ a_2=\alpha_2-\beta_2,\ a_3=\alpha_3-\beta_3,\ a_4=\alpha_4-\beta_4+\gamma_4.$$

Now we have an obvious left parametrix for $I+\mathcal{Q}$, in the following sense:

$$\left(I-\mathcal{Q}+\mathcal{Q}^2-\mathcal{Q}^3\right)(I+\mathcal{Q})=I-\mathcal{Q}^4,$$

where $\mathcal{Q}^4$ is of order ≤ -4 so that

$$\mathcal{Q}^4\left(-i\partial_{x_2}U+\nu\partial_{x_1}^2U+\sum_{0\le j\le 4}T_{a_j}\partial_{x_1}^{1-j}U\right)\in H^{s+2}(\mathbf{T}^2).$$

This gives (5.56).

The symmetries of the coefficients a_j can be checked on the explicit expressions which are involved. Indeed, it follows from (5.50) that the function $s=(s_0,\dots,s_4)$ given by Lemma 5.36 satisfies the same symmetry as S does: given $\varepsilon\in\{-1,+1\}$ and $0\le j\le 4$, we have

$$S(x^\star,\xi^\star)=\varepsilon S(x,\xi)\ \Rightarrow S_j(x^\star)=\varepsilon(-1)^jS_j(x).$$

This concludes the proof of Proposition 5.28.

5.10 Proof of Proposition 5.27

Given Proposition 5.28, the proof of Proposition 5.27 reduces to establishing the following result.

Notation 5.38. Given five complex-valued functions $a_0,\dots,a_4$, we define

$$Z_a=\sum_{0\le j\le 4}T_{a_j}\partial_{x_1}^{-j}.$$

Proposition 5.39. *There exist two constant $\kappa,\kappa'\in\mathbf{R}$ and five functions $c_0,\dots,c_4$ with $c_j\in C^{6-j}(\mathbf{T}^2)$ satisfying $|c_0|>0$ and*

$$c_k \text{ is even in } x_1 \text{ for } k\in\{0,2,4\},\quad c_k \text{ is odd in } x_1 \text{ for } k\in\{1,3\},\tag{5.57}$$

such that

$$Z_c\Big(-i\partial_{x_2}+\nu\partial_{x_1}^2+Z_a\partial_{x_1}\Big)U=\Big(-i\partial_{x_2}+\nu\partial_{x_1}^2+\kappa+\kappa'\partial_{x_1}^{-2}\Big)Z_cU+f,\tag{5.58}$$

where $f\in H^{s+2}(\mathbf{T}^2)$.

Proof. The equation (5.58) is equivalent to a sequence of five transport equations for the coefficients c_j $(0 \le j \le 4)$, which can be solved by induction. Indeed, directly from the Leibniz rule we compute that

$$(-i\partial_{x_2} u + \nu \partial_{x_1}^2 + \kappa + \kappa' \partial_{x_1}^{-2}) Z_c u - Z_c(-i\partial_{x_2} U + \nu \partial_{x_1}^2) u = Z_\delta \partial_{x_1} U,$$

where

$$\begin{aligned}
\delta_0 &= 2\nu \partial_{x_1} c_0, \\
\delta_1 &= 2\nu \partial_{x_1} c_1 - i\partial_{x_2} c_0 + \nu \partial_{x_1}^2 c_0 + c_0 \kappa, \\
\delta_2 &= 2\nu \partial_{x_1} c_2 - i\partial_{x_2} c_1 + \nu \partial_{x_1}^2 c_1 + c_1 \kappa, \\
\delta_3 &= 2\nu \partial_{x_1} c_3 - i\partial_{x_2} c_2 + \nu \partial_{x_1}^2 c_2 + c_2 \kappa + c_0 \kappa', \\
\delta_4 &= 2\nu \partial_{x_1} c_4 - i\partial_{x_2} c_3 + \nu \partial_{x_1}^2 c_3 + c_3 \kappa + c_1 \kappa'.
\end{aligned}$$

On the other hand, if (5.57) is satisfied, then we can apply Proposition 5.31 and its corollary to obtain

$$Z_c Z_a \partial_{x_1} U = Z_{\delta'} \partial_{x_1} U + f,$$

where $f \in H^{s+2}(\mathbf{T}^2)$ and

$$\delta'_k = \sum_{l+m+n=k} c_l (-\partial_{x_1})^m a_n \qquad (0 \le k, l, m, n \le 4).$$

Hence, our purpose is to define $c = (c_0, \dots, c_4)$ satisfying (5.57) and two constants κ and κ' such that

$$\delta = \delta'.$$

STEP 1: Definition of c_0. We first define the principal symbol c_0 by solving the equation $\delta_0 = \delta'_0$, which reads

$$2\nu \partial_{x_1} c_0 = c_0 a_0.$$

We get a unique solution of this equation by imposing the initial condition $c_0(0, x_2) = C_0(x_2)$ on $x_1 = 0$, where C_0 is to be determined. That is, we set

$$c_0(x) = C_0(x_2) e^{\gamma(x)/(2\nu)},$$

where

$$\gamma := \partial_{x_1}^{-1} a_0.$$

Since a_0 is odd in x_1, we have $\int_{-\pi}^{\pi} a_0 \, dx_1 = 0$ and hence

$$\partial_{x_1} \gamma = a_0.$$

Note that, directly from the definition, we have

$$\gamma \in C^{s-6}(\mathbf{T}^2), \quad \gamma \in C(e, e), \quad \int_{-\pi}^{\pi} \gamma \, dx_1 = 0, \quad \gamma(x) \in i\mathbf{R}.$$

STEP 2: Definition of c_1, C_0 and κ. We next define c_1 by solving $\delta_1 = \delta_1'$. This yields

$$2\nu\partial_{x_1}c_1 - a_0 c_1 = G_1$$

with

$$G_1 := i\partial_{x_2}c_0 - \nu\partial^2_{x_1}c_0 - \kappa c_0 + c_0 a_1 - c_0\partial_{x_1}a_0$$

where κ is determined later. We impose the initial condition $c_1(0, x_2) = 0$ on $x_1 = 0$, so that

$$c_1(x_1, x_2) := \frac{1}{2\nu}e^{\gamma/(2\nu)}\int_0^{x_1} e^{-\gamma/(2\nu)}G_1\, ds.$$

Note that c_1 is 2π-periodic in x_1 if and only if

$$\int_0^{2\pi} e^{-\gamma/(2\nu)}G_1\, dx_1 = 0. \tag{5.59}$$

Directly from the definition of G_1, we compute that

$$G_1 = e^{\gamma/(2\nu)}\left[i\partial_{x_2}C_0 + C_0\left(\frac{i}{2\nu}\partial_{x_2}\gamma - \kappa + a_1 - \frac{3}{2}\partial_{x_1}a_0 - \frac{1}{4\nu}a_0^2\right)\right],$$

Using

$$\int_0^{2\pi}\partial_{x_1}a_0\, dx_1 = 0 = \int_0^{2\pi}\gamma\, dx_1,$$

this gives

$$\int_0^{2\pi} e^{\gamma/(2\nu)}G_1\, dx_1 = 2i\pi C_0'(x_2) + C_0(x_2)\int_0^{2\pi}\left[-\kappa + a_1 - \frac{a_0^2}{4\nu}\right]dx_1.$$

Set

$$\beta(x_2) := -2\pi\kappa + \int_0^{2\pi}\left(a_1 - \frac{a_0^2}{4\nu}\right)dx_1. \tag{5.60}$$

so that

$$\int_0^{2\pi} e^{-\gamma/(2\nu)}G_1\, dx_1 = 2i\pi C_0'(x_2) + \beta(x_2)C_0(x_2).$$

We thus define κ by

$$\kappa = \frac{1}{|\mathbf{T}^2|}\iint_{\mathbf{T}^2}\left(a_1 - \frac{a_0^2}{4\nu}\right)dx_1 dx_2. \tag{5.61}$$

With this choice, we have

$$\int_0^{2\pi\ell}\beta(s)\, ds = 0.$$

and hence

$$C_0(x_2) := \exp\left(-\frac{1}{2i\pi}\int_0^{x_2}\beta(s)\,ds\right) \text{ is } 2\pi\ell\text{-periodic in } x_2.$$

With this particular choice of C_0, the condition (5.59) is satisfied and hence c_1 is bi-periodic.

Moreover, directly from these definitions, we have $C_0 \in C^6$ and, by performing an integration by parts to handle the term $\int_0^{x_1} e^{\gamma/(2\nu)}(\partial^2 c_1/\partial {x_1}^2)\,ds$, we obtain that $c_1 \in C^5(\mathbf{T}^2)$.

STEP 3: $\kappa \in \mathbf{R}$. It remains to prove that $\kappa \in \mathbf{R}$. To do this, we first observe that $a_0(x) = A(x,0,1)$ where A is given by Proposition 5.22. In particular we easily check that $a_0(x) \in i\mathbf{R}$ so that $a_0(x)^2 \in \mathbf{R}$. On the other hand, we claim that

$$\operatorname{Im} a_1(x) \text{ is odd in } x_2, \tag{5.62}$$

so that

$$\kappa = \frac{1}{|\mathbf{T}^2|}\iint_{\mathbf{T}^2}\left(\operatorname{Re} a_1 - \frac{a_0^2}{4\nu}\right)dx_1dx_2 \in \mathbf{R}.$$

To prove (5.62), still with the notations of Proposition 5.22 and Lemma 5.30, we first observe that the identity (5.50) and the definition of a_1 imply that

$$\begin{aligned}
a_1(x) &= \frac{1}{i\nu}(\partial_{\xi_1}\tilde{A})(x,\xi) + \tilde{B}_0(x,\xi)\,\Big|_{\xi=(0,1)} \\
&= \frac{1}{i\nu}\partial_{\xi_1}\left(A(x,\xi) - \frac{i\xi_1}{|\xi| + |\xi_2|}\right) + B_0(x,\xi)\,\Big|_{\xi=(0,1)} \\
&= \frac{1}{i\nu}(\partial_{\xi_1}A)(x,0,1) - \frac{1}{2\nu} + B_0(x,0,1),
\end{aligned}$$

so that $\operatorname{Im} a_1(x) = \operatorname{Im} B_0(x,0,1)$.

Now, we claim that

$$\operatorname{Im} B_0(x,-\xi) = -\operatorname{Im} B_0(x,\xi). \tag{5.63}$$

Indeed, this follows from the definition of B_0 (cf Proposition 5.22) and the following symmetry of the symbol λ_σ of the Dirichlet to Neumann operator

$$\overline{\lambda_\sigma(x,\xi)} = \lambda_\sigma(x,-\xi). \tag{5.64}$$

That (5.64) has to be true is clear since this symmetry means nothing more than the fact that $G(\sigma)f$ is real-valued for any real-valued function f.

Once (5.63) is granted, using $B \in \Gamma(e,e)$ we obtain the desired result:

$$\begin{aligned}
\operatorname{Im} a_1(x_1,-x_2) &= \operatorname{Im} B_0(x_1,-x_2,0,1) \\
&= -\operatorname{Im} B_0(x_1,-x_2,0,-1) \\
&= -\operatorname{Im} B_0(x_1,x_2,0,1) \\
&= -\operatorname{Im} a_1(x_1,x_2).
\end{aligned}$$

STEP 4: General formula. We can now give the scheme of the analysis. For $k = 2, 3, 4$, we shall define c_k inductively by

$$2\nu\partial_{x_1}\left(e^{-\gamma/(2\nu)}c_k\right) = e^{-\gamma/(2\nu)}G_k,$$

where G_k is to be determined by means of the equation $\delta_k = \delta'_k + \delta''_{k-1}$. That is, we set

$$c_k(x_1, x_2) = \exp\left(\frac{\gamma(x_1, x_2)}{2\nu}\right)(C_k(x_2) + \Gamma_k(x_1, x_2)),$$

where C_k is to be determined and Γ_k is given by

$$\Gamma_k(x_1, x_2) = \frac{1}{2\nu}\int_0^{x_1} \exp\left(\frac{-\gamma(s, x_2)}{2\nu}\right) G_k(s, x_2)\, ds.$$

As in the previous step, we have to chose the initial data $C_{k-1}(x_2) = c_{k-1}(0, x_2)$ such that Γ_k is 2π-periodic in x_1. Now we note the following fact: Starting from the fact that a_0, a_2, a_4 are odd in x_1 and a_1, a_3 are even in x_1, we successively check that: c_1 is odd in x_1; G_2 is odd in x_1; c_2 is even in x_1; G_3 is even in x_1; c_3 is odd in x_1; G_4 is odd in x_1. As a result, we have

$$\int_{-\pi}^{\pi} e^{-\gamma/(2\nu)}G_2\, dx_1 = 0 = \int_{-\pi}^{\pi} e^{-\gamma/(2\nu)}G_4\, dx_1,$$

which in turn implies that Γ_2 and Γ_4 are bi-periodic. Consequently, one can impose

$$C_1(x_2) = c_1(0, x_2) = 0 \quad \text{and} \quad C_3(x_2) = c_3(0, x_2) = 0.$$

Moreover, we impose $C_4 = 0$ (there is no restriction on C_4 since we stop the expansion at this order). Therefore, it remains only to prove that one can so define C_2 and κ' that Γ_3 is bi-periodic.

STEP 5: Definition of C_2 and κ'. We turn to the details and compute that

$$G_3 = i\partial_{x_2}c_2 - \nu\partial_{x_1}^2 c_2 - (\kappa + \partial_{x_1}a_0 - a_1)c_2 - \kappa' c_0 + c_0 a_3 + c_1 a_2 - c_1\partial_{x_1}a_1.$$

The function c_3 is 2π-periodic in x_1 if and only if

$$\int_0^{2\pi} e^{-\gamma/(2\nu)}G_3\, dx_1 = 0. \tag{5.65}$$

Directly from the definition of G_3, we have

$$\begin{aligned}
&\int_0^{2\pi} e^{-\gamma/(2\nu)} G_3 \, dx_1 \\
&\qquad = 2i\pi C_2'(x_2) + C_2(x_2) \int_0^{2\pi} \left(-\kappa + a_1 - \frac{a_0^2}{4\nu} \right) dx_1 \\
&\qquad\quad + \Gamma_2(x_1, x_2) \int_0^{2\pi} \left(\frac{i}{2\nu} \partial_{x_2} \gamma - \kappa + a_1 - \frac{3}{2} \partial_{x_1} a_0 - \frac{1}{4\nu} a_0^2 \right) dx_1 \\
&\qquad\quad + \int_0^{2\pi} \left(i \partial_{x_2} \Gamma_2 - \nu \partial_{x_1}^2 \Gamma_2 - \partial_{x_1} \gamma \partial_{x_1} \Gamma_2 \right) dx_1 \\
&\qquad\quad + \int_0^{2\pi} (a_3 - \kappa') C_0 \, dx_1.
\end{aligned}$$

Now since a_3 is odd in x_1, the last term simplifies to $-2\pi\kappa' C_0(x_2)$. Note also that

$$\int_0^{2\pi} \partial_{x_1}^2 \Gamma_2 \, dx_1 = 0,$$

and

$$\int_0^{2\pi} -\partial_{x_1} \gamma \partial_{x_1} \Gamma_2 \, dx_1 = \int_0^{2\pi} -a_0 \partial_{x_1} \Gamma_2 \, dx_1 = \int_0^{2\pi} \Gamma_2 \partial_{x_1} a_0 \, dx_1.$$

By using the previous cancelations, we obtain that for (5.65) to be true, a sufficient condition is that C_2 solves the equation

$$2i\pi C_2'(x_2) + \beta(x_2) C_2(x_2) = F_2(x_2) - 2\pi\kappa' C_0(x_2), \tag{5.66}$$

with

$$F_2(x_2) := \int_0^{2\pi} \left(\frac{i}{2\nu} \partial_{x_2} \gamma - \kappa + a_1 - \frac{1}{2} \partial_{x_1} a_0 - \frac{1}{4\nu} a_0^2 \right) \Gamma_2 + i \partial_{x_2} \Gamma_2 \, dx_1.$$

If we impose the initial condition $C_2 = 1$ on $x_2 = 0$, then equation (5.66) has a $2\pi\ell$-periodic solution if and only if κ' is given by

$$\kappa' := \frac{1}{|\mathbf{T}^2|} \int_0^{2\pi\ell} \exp\left(\frac{1}{2i\pi} \int_0^{x_2} \beta(s) \, ds \right) F_2(x_2) \, dx_2.$$

We are then in position to define a function C_2 such that c_3 is bi-periodic.

Step 6: $\kappa' \in \mathbf{R}$. It remains to prove that $\kappa' \in \mathbf{R}$. Firstly, observe that similar arguments to those used in the third step establish that

$$\overline{a_k(x_1, x_2)} = a_k(x_1, -x_2) \quad \text{for } 0 \leq k \leq 4. \tag{5.67}$$

Then, we successively check that

$$\begin{aligned}
\overline{c_0(x_1, x_2)} &= c_0(x_1, -x_2), \\
\overline{c_1(x_1, x_2)} &= c_1(x_1, -x_2), \\
\overline{c_2(x_1, x_2)} &= c_2(x_1, -x_2).
\end{aligned} \tag{5.68}$$

To complete the proof we express κ' as a function of these coefficients.

Lemma 5.40. *There holds*

$$
\begin{aligned}
\kappa' = \frac{1}{|\mathbf{T}|^2} \iint_{\mathbf{T}^2} \frac{c_2}{c_0} \left(\frac{i}{2\pi} \partial_{x_2}\gamma + a_1 - \frac{1}{2}\partial_{x_1} a_0 - \frac{1}{4\nu} a_0^2 - \kappa \right) dx_1 dx_2 \\
+ \frac{1}{|\mathbf{T}|^2} \iint_{\mathbf{T}^2} \frac{c_1}{c_0} \left(a_2 - \partial_{x_1} a_1 + \partial_{x_1}^2 a_0 \right) dx_1 dx_2
\end{aligned}
\tag{5.69}
$$

Proof. Introduce

$$
\gamma_1 = \frac{c_1}{c_0}, \quad \gamma_2 = \frac{c_2}{c_0}, \quad \gamma_3 = \frac{c_3}{c_0}.
$$

With this notation, directly from the equation $\delta_3 = \delta_3'$ we have

$$
\begin{aligned}
\kappa' = {} & -2\nu\partial_{x_1}\gamma_3 - \frac{\beta}{2\pi}\gamma_2 + \frac{i}{2\nu}(\partial_{x_2}\gamma)\gamma_2 \\
& - \nu\partial_{x_1}^2\gamma_2 - \frac{1}{2}a_0\partial_{x_1}\gamma_2 - \frac{1}{4\nu}a_0^2\gamma_2 + \frac{1}{2}(\partial_{x_1}a_0)\gamma_2 - \kappa\gamma_2 \\
& + a_3 - \partial_{x_1}a_2 + \partial_{x_1}^2 a_1 - \partial_{x_1}^3 a_0 + \gamma_1 a_2 - \gamma_1\partial_{x_1}a_1 + \gamma_1\partial_{x_1}^2 a_0 \\
& + \gamma_2 a_1 - \gamma_2\partial_{x_1}a_0,
\end{aligned}
$$

where we used various cancelations. By integrating over $\mathbf{T}^2$, taking into accounts obvious cancelations of the form $\int_{-\pi}^{\pi} \partial_{x_1} f \, dx_1 = 0$ and integrating by parts in x_1 the term $\iint a_0 \partial_{x_1}\gamma_2 \, dx_1 dx_2$, we obtain the desired identity. □

Using (5.69), (5.67) and (5.68), we obtain $\overline{\kappa'} = \kappa'$ and hence $\kappa' \in \mathbf{R}$.

This completes the proof of the proposition, and hence of Theorem 2.5. □

6 The small divisor condition for families of diamond waves

In this section, we prove Proposition 2.10, whose statement is recalled here.

Proposition 6.1. *Let δ and δ' be such that*

$$
1 > \delta > \delta' > 0.
$$

Let $\nu = \nu(\varepsilon)$, $\kappa_0 = \kappa_0(\varepsilon)$ and $\kappa_1 = \kappa_1(\varepsilon)$ be three real-valued functions defined on $[0,1]$ such that

$$
\begin{aligned}
\nu(\varepsilon) &= \underline{\nu} + \underline{\nu}'\varepsilon^2 + \varepsilon\varphi_1(\varepsilon^2), \\
\kappa_0(\varepsilon) &= \underline{\kappa_0} + \varphi_2(\varepsilon^2), \\
\kappa_1(\varepsilon) &= \underline{\kappa_1} + \varphi_3(\varepsilon^2),
\end{aligned}
\tag{6.1}
$$

for some constants $\underline{\nu}, \underline{\nu}', \underline{\kappa_0}, \underline{\kappa_1}'$ with

$$
\underline{\nu}' \neq 0,
$$

and three Lipschitz functions $\varphi_j\colon [0,1] \to \mathbf{R}$ *satisfying* $\varphi_j(0) = 0$*. Assume in addition that there exists* $n \geq 2$ *such that*

$$\left| k_2 - \underline{\nu} k_1^2 - \underline{\kappa_0} \right| \geq \frac{1}{k_1^{1+\delta'}}, \tag{6.2}$$

for all $k \in \mathbf{N}^2$ *with* $k_1 \geq n$*. Then there exist* $K > 0$*,* $r_0 > 0$*,* $N_0 \in \mathbf{N}$ *and a set* $\mathcal{A} \subset [0,1]$ *satisfying*

$$\forall r \in [0, r_0], \quad \frac{1}{r} \left| \mathcal{A} \cap [0,r] \right| \geq 1 - K r^{\frac{\delta - \delta'}{3+\delta'}},$$

such that, if $\varepsilon^2 \in \mathcal{A}$ *and* $k_1 \geq N_0$ *then*

$$\left| k_2 - \nu(\varepsilon) k_1^2 - \kappa_0(\varepsilon) - \frac{\kappa_1(\varepsilon)}{k_1^2} \right| \geq \frac{1}{k_1^{2+\delta}},$$

for all $k_2 \in \mathbf{N}$*.*

Proof. As in [22], it is convenient to introduce

$$\lambda = \varepsilon^2, \ \tilde{\nu}(\lambda) = \nu(\sqrt{\lambda}), \ \tilde{\kappa}_0(\lambda) = \kappa_0(\sqrt{\lambda}), \ \tilde{\kappa}_1(\lambda) = \kappa_1(\sqrt{\lambda}).$$

Introduce also the notations

$$d(k) = d(k_1, k_2) := \frac{k_2}{k_1^2} - \underline{\nu} - \frac{\underline{\kappa_0}}{k_1^2} - \frac{\underline{\kappa_1}}{k_1^4}$$

and

$$\omega(\lambda, k_1) := \tilde{\nu}(\lambda) - \underline{\nu} + \frac{\tilde{\kappa}_0(\lambda) - \underline{\kappa_0}}{k_1^2} + \frac{\tilde{\kappa}_1(\lambda) - \underline{\kappa_1}}{k_1^4}.$$

By assumption,

$$\omega(\lambda, k_1) = \underline{\nu}' \lambda + \lambda^{\frac{1}{2}} \varphi_1(\lambda) + \frac{\varphi_2(\lambda)}{k_1^2} + \frac{\varphi_3(\lambda)}{k_1^4},$$

where $\varphi_j(\lambda)$ $(j = 1,2,3)$ is a Lipschitz function vanishing at the origin. Therefore, for k_1 large enough and λ small enough, we have

$$\frac{|\underline{\nu}'|}{2} \lambda \leq |\omega(\lambda, k_1)| \leq 2 \left| \underline{\nu}' \right| \lambda. \tag{6.3}$$

Similarly, for k_1 large enough and λ, λ' small enough,

$$\frac{|\underline{\nu}'|}{2} \left| \lambda - \lambda' \right| \leq \left| \omega(\lambda, k_1) - \omega(\lambda', k_1) \right|. \tag{6.4}$$

Given $r > 0$ and $N \in \mathbf{N}^*$, introduce the set

$$\mathcal{A}(r, N) = \bigcap_{k_2 \in \mathbf{N}} \bigcap_{\mathbf{N} \ni k_1 \geq N} \left\{ \lambda \in [0, r] \, : \, |d(k_1, k_2) - \omega(\lambda, k_1)| \geq \frac{1}{k_1^{4+\delta}} \right\}.$$

We have to prove that there exist $r_0 > 0$, $K > 0$ and $N_0 \in \mathbf{N}^*$ such that

$$\forall r \in]0, r_0], \quad |[0,r] \setminus \mathcal{A}(r, N_0)| \leq K r^{1+\frac{\delta-\delta'}{3+\delta'}}. \tag{6.5}$$

Note that for $n \in \mathbf{N}^*$,

$$[0,r] \setminus \mathcal{A}(r, N) = \bigcup_{k_1 \geq N} \bigcup_{k_2 \in \mathbf{N}} E(r, k_1, k_2)$$

with

$$E(r, k_1, k_2) = \left\{ \lambda \in [0,r] : |d(k_1, k_2) - \omega(\lambda, k_1)| < \frac{1}{k_1^{4+\delta}} \right\}.$$

The proof then depends on the following lemma.

Lemma 6.2. *There exist $r_0 > 0$, $N_0 \in \mathbf{N}$ and three positive constant A_j, $j = 1, 2, 3$,such that, for all $r \in [0, r_0]$, for all $k_1 \geq N_0$ and for all $k_2 \in \mathbf{N}$, we have*

1. *If $E(r, k_1, k_2) \neq \emptyset$ then*
$$k_1 \geq A_1 r^{-\frac{1}{3+\delta'}}. \tag{6.6}$$
2. $\# \{ m \in \mathbf{N} : E(r, k_1, m) \neq \emptyset \} \leq A_2 (r k_1^2 + 1)$.
3. $|E(r, k_1, k_2)| \leq A_3 k_1^{-4-\delta}$.

Assume this lemma for a moment and continue the proof. This lemma implies that, for $r \in [0, r_0]$ and $k_1 \geq N_0$, we have

$$\left| \bigcup_{k_2 \in \mathbf{N}} E(r, k_1, k_2) \right| \leq A_2 A_3 \frac{r k_1^2 + 1}{k_1^{4+\delta}}.$$

Consequently,

$$\begin{aligned} |[0,r] \setminus \mathcal{A}(r, N_0)| &\leq A_2 A_3 \sum_{k_1 \geq A_1 r^{-\frac{1}{3+\delta'}}} \frac{r k_1^2 + 1}{k_1^{4+\delta}} \\ &\leq A \left\{ r \times r^{\frac{1+\delta}{3+\delta'}} + r^{\frac{3+\delta}{3+\delta'}} \right\}, \end{aligned}$$

for some positive constant A independent of r, which yields the desired bound (6.5).

It remains to prove Lemma 6.2. Suppose that $E(r, k_1, k_2) \neq \emptyset$ and chose $\lambda \in E(r, k_1, k_2)$. To prove (6.6), we first use assumption (6.2) which reads

$$\frac{1}{k_1^{3+\delta'}} \leq \left| \frac{k_2}{k_1^2} - \underline{\nu} - \frac{\underline{\kappa_0}}{k_1^2} \right|,$$

for k_1 large enough. Hence, by definition of $d(k_1, k_2)$,

$$\frac{1}{k_1^{3+\delta'}} \leq |d(k_1, k_2)| + \frac{|\underline{\kappa_1}|}{k_1^4}.$$

Now, by the triangle inequality, we have

$$\frac{1}{k_1^{3+\delta'}} \leq |d(k_1, k_2) - \omega(\lambda, k_1)| + |\omega(\lambda, k_1)| + \frac{|\underline{\kappa_1}|}{k_1^4}.$$

By definition, if $\lambda \in E(r, k_1, k_2)$ then the first term in the right hand side is bounded by $k_1^{-4-\delta}$, so

$$\frac{1}{k_1^{3+\delta'}} \leq \frac{1}{k_1^{4+\delta}} + |\omega(\lambda, k_1)| + \frac{|\underline{\kappa_1}|}{k_1^4}.$$

Hence, since $0 < \delta$ and $\delta' < 1$, we have

$$\frac{1}{2} \frac{1}{k_1^{3+\delta'}} \leq |\omega(\lambda, k_1)|,$$

for k_1 large enough. Now we use the simple estimate (6.3) valid for k_1 large enough and λ small enough, to obtain

$$\frac{1}{k_1^{3+\delta'}} \leq 4 |\underline{\nu}'| \lambda \leq 4 |\underline{\nu}'| r.$$

This establishes the first claim in Lemma 6.2.

To prove the second claim, note that, given $r > 0$ and k_1, if $E(r, k_1, k_2) \neq \emptyset$ and $E(r, k_1, k_2') \neq \emptyset$ then exist λ and λ' such that

$$|d(k_1, k_2) - \omega(\lambda, k_1)| \leq \frac{1}{k_1^{4+\delta}}, \quad |d(k_1, k_2') - \omega(\lambda', k_1)| \leq \frac{1}{k_1^{4+\delta}}.$$

Now by the triangle inequality, using (6.3), this yields

$$\begin{aligned}
&\left| \frac{k_2}{k_1^2} - \frac{k_2'}{k_1^2} \right| = \\
&\quad = |d(k_1, k_2) - d(k_1, k_2')| \\
&\quad \leq |d(k_1, k_2) - \omega(\lambda, k_1)| + |d(k_1, k_2') - \omega(\lambda', k_1)| + |\omega(\lambda, k_1) - \omega(\lambda', k_1)| \\
&\quad \leq \frac{2}{k_1^{4+\delta}} + 2 |\underline{\nu}'| (\lambda + \lambda') \leq \frac{2}{k_1^{4+\delta}} + 4 |\underline{\nu}'| r.
\end{aligned}$$

Multiplying both sides by k_1^2 we obtain the bound

$$|k_2 - k_2'| \leq \frac{2}{k_1^{2+\delta}} + 4\,|\underline{\nu}'|\, r k_1^2,$$

and hence

$$\#\,\{m \in \mathbf{N}\,:\, E(r, k_1, m) \neq \emptyset\} \leq 1 + \frac{2}{k_1^{2+\delta}} + 4\,|\underline{\nu}'|\, r k_1^2.$$

It remains to prove the last claim. Introduce

$$\lambda_{min}(r, k_1, k_2) = \inf E(r, k_1, k_2), \quad \lambda_{max}(r, k_1, k_2) = \sup E(r, k_1, k_2).$$

Then, using (6.4) we find

$$\begin{aligned}
|E(r, k_1, k_2)| &\leq \lambda_{max}(r, k_1, k_2) - \lambda_{min}(r, k_1, k_2) \\
&\leq \frac{2}{|\underline{\nu}'|}\left|\omega\big(\lambda_{max}(r, k_1, k_2), k_1\big) - \omega\big(\lambda_{min}(r, k_1, k_2), k_1\big)\right| \\
&\leq \frac{2}{|\underline{\nu}'|}\left|\omega\big(\lambda_{max}(r, k_1, k_2), k_1\big) - d(k_1, k_2)\right| \\
&\quad + \left|d(k_1, k_2) - \omega\big(\lambda_{min}(r, k_1, k_2), k_1\big)\right| \\
&\leq \frac{4}{|\underline{\nu}'|} k_1^{-4-\delta}.
\end{aligned}$$

This completes the proof of Lemma 6.2 and hence the proof of Proposition 2.10. ☐

Remark 6.3. The previous proof follows essentially the analysis in [22]. The key difference is that, in [22], the authors need to prove that a diophantine condition of the form

$$\left|k_2 - \nu(\varepsilon)k_1^2 - \kappa_0(\varepsilon)\right| \geq \frac{1}{k_1^2}, \tag{6.7}$$

is satisfied for all $\varepsilon^2 \in \mathcal{A}$ for some set $\mathcal{A}$ satisfying

$$\lim_{r \to 0} \frac{1}{r}\,|\mathcal{A} \cap [0, r]| = 1.$$

This corresponds to the case $\delta = 0$ of the above theorem (which we precluded by assumption). Now, observe that in this case the above analysis only gives

$$|[0, r] \setminus \mathcal{A}(r, N_0)| \lesssim r^{\frac{3}{3+\delta'}}.$$

Then to pass from this bound to $|[0, r] \setminus \mathcal{A}(r, N_0)| = o(r)$, one has to gain extra decay in r. To do this, Iooss and Plotnikov use an ergodic argument. What makes the proof of the above Theorem simple is that we proved only that a weaker diophantine condition is satisfied. (Here "weaker diophantine condition" refers to the fact that, if (6.7) is satisfied then (2.9) is satisfied for any $\delta \geq 0$.) In particular, this discussion clearly shows that it is simpler to prove that (2.3) is satisfied for some $\delta > 0$ than for $\delta = 0$. This gives a precise meaning to what we claimed in the introduction: our paradifferential strategy may be used to simplify the analysis of the small divisors problems.

7 Two elliptic cases

7.1 When the Taylor condition is not satisfied

Consider a classical C^2 solution (σ, ϕ) of the system

$$\begin{cases} G(\sigma)\psi = f_1 \in C^\infty(\mathbf{T}^2), \\ \mu\sigma + \dfrac{1}{2}\left|\nabla\psi\right|^2 - \dfrac{1}{2}\dfrac{(\nabla\sigma\cdot\nabla\psi)^2}{1+|\nabla\sigma|^2} = f_2 \in C^\infty(\mathbf{T}^2), \end{cases} \tag{7.1}$$

where $x \in \mathbf{T}^2$, and f_1, f_2 are given C^∞ functions.

Our goal here is to show that the problem is much easier in the case where the Taylor sign condition is not satisfied. To make this more precise, set

$$\mathfrak{a} := \mu + V\cdot\nabla\mathfrak{b} \quad \text{with} \quad \mathfrak{b} := \frac{\nabla\sigma\cdot\nabla\psi}{1+|\nabla\sigma|^2}, \quad V := \nabla\psi - \mathfrak{b}\nabla\sigma.$$

We prove a *local* hypoellipticity result near boundary points $(x, \sigma(x))$ where $\mathfrak{a} < 0$. We prove that, if $\sigma \in H^s$ and $\phi \in H^s$ for some $s > 3$ near a boundary point $(x_0, \sigma(x_0))$ such that $\mathfrak{a}(x_0) < 0$, then σ, ϕ are C^∞ near $(x_0, \sigma(x_0))$. (This can be improved; the result remains valid under the weaker assumption that $\sigma, \phi \in C^s$ with $s > 2$ for $x \in \mathbf{T}^d$ with $d \geq 1$. Yet, we will not address this issue.)

The main observation is that, in the case where $\mathfrak{a} < 0$, the boundary problem (7.1) is weakly elliptic. Consequently, any term which has the regularity of the unknowns can be seen as an admissible remainder for the paralinearization of the first boundary condition (that is why we can localize the estimates). In addition, the fact that the problem is weakly elliptic implies that we can obtain the desired sub-elliptic estimates by a simple integration by parts argument. To localize in Sobolev space, we use the following notation: given an open subset $\omega \subset \mathbf{R}^d$ and a distribution $u \in \mathcal{S}'(\mathbf{R}^d)$, we say that $u \in H^s(\omega)$ if $\chi u \in H^s(\mathbf{R}^d)$ for every $\chi \in C_0^\infty(\omega)$.

Theorem 7.1. *Let $s > 4$ and consider an open domain $\omega \subset\subset \mathbf{T}^2$. Suppose that $(\sigma, \psi) \in H^s(\omega)$ satisfies System 7.1 and $\mathfrak{a}(x) < 0$ for all $x \in \omega$. Then, for all $\omega' \subset\subset \omega$, there holds $(\sigma, \psi) \in H^{s+1/2}(\omega')$.*

Proof. By using symbolic calculus, we begin by observing that we have a localization property. Consider two cutoff functions $\chi' \in C_0^\infty(\omega')$ and $\chi \in C_0^\infty(\mathbf{R}^d)$ such that $\chi = 1$ on ω and $\chi' = 1$ on ω'. Then $\tilde{u} = \chi'\psi - T_{\chi\mathfrak{b}}\chi'\sigma$ and $\tilde{\sigma} = \chi'\sigma$ satisfy

$$T_{\lambda_\sigma^1}\tilde{u} - T_V \cdot \nabla\tilde{\sigma} = \psi \in H^s(\omega'), \tag{7.2}$$

$$T_{\mathfrak{a}}\tilde{\sigma} + T_V \cdot \nabla\tilde{u} = \theta \in H^{2s-3}(\omega'), \tag{7.3}$$

where recall that

$$\lambda_\sigma^1(x,\xi) = \sqrt{(1+|\nabla\sigma(x)|^2)|\xi|^2 - (\nabla\sigma(x)\cdot\xi)^2}.$$

The strategy of the proof is very simple: We next form a second order equation from (7.2)-(7.3). The assumption $\mathfrak{a}(x_0) < 0$ implies that the operator thus obtained is quasi-homogeneous elliptic, which implies the desired sub-elliptic regularity for System (7.2)–(7.3). Namely, we claim that $\tilde{u} \in H^{\alpha+\frac{1}{2}}(\omega')$ and $\tilde{\sigma} \in H^\alpha(\omega')$ with

$$\alpha := \min\left\{s + \frac{1}{2}, 2s-3\right\} > s.$$

To prove this claim, we set $\Lambda = (1-\Delta)^{\frac{1}{2}}$ and use the Gårding's inequality for paradifferential operators, to obtain that there are constants C and $c > 0$ such that

$$\begin{aligned}
\Re\left(T_V \cdot \nabla\tilde{\sigma}, \Lambda^{2\alpha}\tilde{u}\right)_{L^2} + \left(T_V \cdot \nabla\tilde{u}, \Lambda^{2\alpha}\tilde{\sigma}\right)_{L^2} &\le C\left\|\tilde{u}\right\|_{H^\alpha}\left\|\tilde{\sigma}\right\|_{H^\alpha},\\
c\left\|\tilde{u}\right\|^2_{H^{\alpha+\frac{1}{2}}} &\le \Re\left(T_{\lambda_\sigma^1}\tilde{u}, \Lambda^{2\alpha}\tilde{u}\right)_{L^2} + C\left\|\tilde{u}\right\|^2_{H^\alpha},\\
c\left\|\tilde{\sigma}\right\|^2_{H^\alpha} &\le \Re\left(T_{\mathfrak{a}}\tilde{\sigma}, -\Lambda^{2\alpha}\tilde{\sigma}\right)_{L^2} + C\left\|\tilde{\sigma}\right\|^2_{H^{\alpha-\frac{1}{2}}}.
\end{aligned}$$

Therefore, taking the scalar product of the equations (7.2) and (7.3) by $\Lambda^{2\alpha}\tilde{u}$ and $-\Lambda^{2\alpha}\tilde{\sigma}$ respectively, and adding the real parts, implies that

$$\begin{aligned}
&c\left\|\tilde{u}\right\|^2_{H^{\alpha+\frac{1}{2}}} + c\left\|\tilde{\sigma}\right\|^2_{H^\alpha}\\
&\quad\le C\left\|\theta\right\|_{H^{\alpha-\frac{1}{2}}}\left\|\tilde{u}\right\|_{H^{\alpha+\frac{1}{2}}} + C\left\|\psi\right\|_{H^\alpha}\left\|\tilde{\sigma}\right\|_{H^\alpha}\\
&\qquad + C\left\|\tilde{u}\right\|_{H^\alpha}\left\|\tilde{\sigma}\right\|_{H^\alpha} + C\left\|\tilde{u}\right\|^2_{H^\alpha} + C\left\|\tilde{\sigma}\right\|^2_{H^{\alpha-\frac{1}{2}}},
\end{aligned}$$

and the claim follows.

As a consequence we find that $\sigma \in H^\alpha(\omega')$ and $u \in H^{\alpha+\frac{1}{2}}(\omega')$. Going back to $\psi = u + T_{\mathfrak{b}}\sigma$, we obtain that $\psi \in H^\alpha(\omega')$. This finishes the proof of the Theorem 7.1. $\square$

7.2 Capillary gravity waves

In this section, we prove *a priori* regularity for the system obtained by adding surface tension:

$$\begin{cases} G(\sigma)\psi - c\cdot\nabla\sigma = 0, \\ \mu\sigma + c\cdot\nabla\psi + \dfrac{1}{2}\left|\nabla\psi\right|^2 - \dfrac{1}{2}\dfrac{\left(\nabla\sigma\cdot\nabla\psi + c\cdot\nabla\sigma\right)^2}{1+|\nabla\sigma|^2} - H(\sigma) = 0, \end{cases}$$

where $H(\sigma)$ denotes the mean curvature of the free surface $\{y=\sigma(x)\}$:

$$H(\sigma) := \operatorname{div}\left(\frac{\nabla\sigma}{\sqrt{1+|\nabla\sigma|^2}}\right).$$

Recently there have been some results concerning *a priori* regularity for the solutions of this system, first for the two-dimensional case by Matei [30], and second for the general case $d\geq 2$ by Craig and Matei [10, 11]. Independently, there is also the paper by Koch, Leoni and Morini [26] which is motivated by the study of the Munford–Shah functional. Craig and Matei proved C^ω regularity for $C^{2+\alpha}$ solutions, and Koch, Leoni and Morini proved this result for C^2 solutions (they also note that the result holds true for C^1 viscosity solutions). Both proofs rely upon the hodograph and Legendre transforms introduced in this context by Kinderlehrer, Nirenberg and Spruck in the well known papers [23, 24, 25]. Here, as a corollary of Theorem 2.12, we prove that C^3 solutions are C^∞, without change of variables, by using the hidden ellipticity given by surface tension. To emphasize this point, the following result is stated in a little more generality than is needed.

Proposition 7.2. *If* $(\sigma,\psi)\in C^3(\mathbf{R}^d)$ *solves a system of the form*

$$\begin{cases} G(\sigma)\psi = f_1 \in C^\infty(\mathbf{R}^d), \\ F(\psi,\nabla\psi,\sigma,\nabla\sigma) + H(\sigma) = f_2 \in C^\infty(\mathbf{R}^d), \end{cases}$$

where F *is a smooth function of its arguments, then* $(\sigma,\psi)\in C^\infty(\mathbf{R}^d)$*.*

Proof. By using standard regularity results for quasi-linear elliptic PDE, we prove that if $(\sigma,\psi)\in C^m$ for some $m\geq 2$, then $(\sigma,\psi)\in C^{m+1-\varepsilon}$ for any $\varepsilon>0$. For instance, it follows from Theorem 2.2.D in [40] that,

$$\sigma\in C^m,\ H(\sigma)\in C^1 \Rightarrow \sigma\in C^{m+1-\delta},$$

for any $\delta>0$. As a result, it follows from the paralinearization formula for the Dirichlet to Neumann operator (cf Remark 2.16 after Theorem 2.12) that,

$$T_{\lambda_\sigma^1}(\psi - T_{\mathfrak{b}}\sigma)\in C^{m-\delta'} \quad \text{for any} \quad \delta'>0,$$

where λ_σ^1 is the principal symbol of the Dirichlet to Neumann operator. Since λ_σ^1 is a first-order elliptic symbol with regularity at least C^1 in x, this implies that $\psi - T_{\mathfrak{b}}\sigma\in C^{m+1-\delta''}$ and hence $\psi\in C^{m+1-\delta''}$ for any $\delta''>0$. □
